

Modern C++ Programming

13. UTILITIES

Federico Busato

University of Verona, Dept. of Computer Science
2021, v3.05

Table of Context

1 I/O Stream

- Manipulator
- `ofstream/ifstream`

2 Math Libraries

3 `std::string`

- `std::string`
- Conversion from/to Numeric Values
- `std::string_view`
- `std::format`

Table of Context

4 Random Number

- Basic Concepts
- C++ <random>
- Seed
- PRNG Period and Quality
- Distribution
- Quasi-random

5 Time Measuring

- Wall-Clock Time
- User Time
- System Time

Table of Context

6 Std Template Classes

- std::pair
- std::tuple
- std::variant
- std::optional
- std::any

7 Filesystem Library

- Query Methods
- Modify Methods

I/O Stream

I/O Stream

`<iostream>` input/output library refers to a family of classes and supporting functions in the C++ Standard Library that implement stream-based input/output capabilities

There are four predefined iostreams:

- `cin` standard input (`stdin`)
- `cout` standard output (`stdout`) [buffered]
- `cerr` standard error (`stderr`) [unbuffered]
- `clog` standard error (`stderr`) [unbuffered]

buffered: the content of the buffer is not write to disk until some events occur

Basic I/O Stream manipulator:

- `flush` flushes the output stream `cout << flush;`
- `endl` shortcut for `cout << "\n" << flush;`
`cout << endl`
- `flush` and `endl` force the program to synchronize with the terminal → very slow operation!

- Set **integral representation**: default: dec

```
cout << dec << 0xF; prints 16
```

```
cout << hex << 16; prints 0xF
```

```
cout << oct << 8; prints 10
```

- Print the underlying **bit representation** of a value:

```
#include <bitset>
std::cout << std::bitset<32>(3.45f); // (32: num. of bits)
// print 01000000010111001100110011001101
```

- Print true/false text:

```
cout << boolalpha << 1; prints true
```

```
cout << boolalpha << 0; prints false
```

```
<iomanip>
```

- **Set decimal precision:** default: 6

```
cout << setprecision(2) << 3.538; → 3.54
```

- **Set float representation:** default: std::defaultfloat

```
cout << setprecision(2) << fixed << 32.5; → 32.50
```

```
cout << setprecision(2) << scientific << 32.5; → 3.25e+01
```

- **Set alignment:** default: right

```
cout << right << setw(7) << "abc" << "##"; → abc##
```

```
cout << left << setw(7) << "abc" << "##"; → abc##
```

(better than using tab \t)

I/O Stream - std::cin

`std::cin` is an example of *input* stream. Data coming from a source is read by the program.
In this example `cin` is the standard input

```
#include <iostream>

int main() {
    int a;
    std::cout << "Please enter an integer value:" << endl;
    std::cin >> a;

    int b;
    float c;
    std::cout << "Please enter an integer value "
        << "followed by a float value:" << endl;
    std::cin >> b >> c; // read an integer and store into "b",
}                                // then read a float value, and store
                                // into "c"
```

`ifstream`, `ofstream` are output and input stream too

`<fstream>`

- **Open a file for reading**

Open a file in input mode: `ifstream my_file("example.txt")`

- **Open a file for writing**

Open a file in output mode: `ofstream my_file("example.txt")`

Open a file in append mode: `ofstream my_file("example.txt", ios::out | ios::app)`

- **Read a line** `getline(my_file, string)`

- **Close a file** `my_file.close()`

- **Check the stream integrity** `my_file.good()`

- **Peek the next character**

```
char current_char = my_file.peek()
```

- **Get the next character (and advance)**

```
char current_char = my_file.get()
```

- **Get the position of the current character in the input stream**

```
int byte_offset = my_file.tellg()
```

- **Set the char position in the input sequence**

```
my_file.seekg(byte_offset) (absolute position)
```

```
my_file.seekg(byte_offset, position) (relative position)
```

where position can be:

- `ios::beg` (the begin), `ios::end` (the end),
- `ios::cur` (current position)

- **Ignore characters until the delimiter is found**

```
my_file.ignore(max_stream_size, <delim>)
```

e.g. skip until end of line \n

- **Get a pointer to the stream buffer object currently associated with the stream**

```
my_file.rdbuf()
```

can be used to redirect file stream

I/O Stream - Example 1

Open a file and print line by line:

```
#include <iostream>
#include <fstream>

int main() {
    std::ifstream fin("example.txt");
    std::string str;
    while (fin.good()) {
        std::getline(fin, str);
        std::cout << str << "\n";
    }
    fin.close();
}
```

An alternative version with redirection:

```
#include <iostream>
#include <fstream>

int main() {
    std::ifstream fin("example.txt");
    std::cout << fin.rdbuf();
    fin.close();
}
```

I/O Stream - Example 2

example.txt:

```
23 70 44\n
\t57\t89
```

The input stream is independent from the type of space (multiple space, tab, new-line \n, \r\n, etc.)

Another example:

```
#include <iostream>
#include <fstream>

int main() {
    std::ifstream fin("example.txt");
    char c = fin.peek(); // c = '2'
    while (fin.good()) {
        int var;
        fin >> var;
        std::cout << var;
    }           // print 2370445789
    fin.seekg(4);
    c = fin.peek(); // c = '0'
    fin.close();
}
```

I/O Stream -Check the End of a File

- Check the current character

```
while (fin.peek() != std::char_traits<char>::eof()) // C: EOF  
    fin >> var;
```

- Check if the read operation fails

```
while (fin >> var)  
    ...
```

- Check if the stream past the end of the file

```
while (true) {  
    fin >> var  
    if (fin.eof())  
        break;  
}
```

I/O Stream (checkRegularType)

Check if a file is a **regular file** and can be read/written

```
#include <sys/types.h>
#include <sys/stat.h>

bool checkRegularFile(const char* file_path) {
    struct stat info;
    if (::stat( file_path, &info ) != 0)
        return false;           // unable to access
    if (info.st_mode & S_IFDIR)
        return false;           // is a directory
    std::ifstream fin(file_path); // additional checking
    if (!fin.is_open() || !fin.good())
        return false;
    try {                      // try to read
        char c; fin >> c;
    } catch (std::ios_base::failure&) {
        return false;
    }
    return true;
}
```

I/O Stream - File size

Get the **file size** in bytes in a **portable** way:

```
long long int fileSize(const char* file_path) {
    std::ifstream fin(file_path);      // open the file
    fin.seekg(0, ios::beg);           // move to the first byte
    std::istream::pos_type start_pos = fin.tellg();          // get the start offset
    fin.seekg(0, ios::end);           // move to the last byte
    std::istream::pos_type end_pos = fin.tellg();            // get the end offset
    return end_pos - start_pos;     // position difference
}
```

see **C++17** file system utilities

Math Libraries

<cmath>

- **fabs(x)** computes absolute value, $|x|$, C++11
- **exp(x)** returns e raised to the given power, e^x
- **exp2(x)** returns 2 raised to the given power, 2^x , C++11
- **log(x)** computes natural (base e) logarithm, $\log_e(x)$
- **log10(x)** computes base 10 logarithm, $\log_{10}(x)$
- **log2(x)** computes base 2 logarithm, $\log_2(x)$, C++11
- **pow(x, y)** raises a number to the given power, x^y
- **sqrt(x)** computes square root, \sqrt{x}
- **cqrt(x)** computes cubic root, $\sqrt[3]{x}$, C++11

- `sin(x)` computes sine, $\sin(x)$
- `cos(x)` computes cosine, $\cos(x)$
- `tan(x)` computes tangent, $\tan(x)$
- `ceil(x)` nearest integer not less than the given value, $\lceil x \rceil$
- `floor(x)` nearest integer not greater than the given value, $\lfloor x \rfloor$
- `round|lround|llround(x)` nearest integer, $\lfloor x + \frac{1}{2} \rfloor$
(return type: floating point, long, long long respectively)

Math functions in C++11 can be applied directly to integral types without implicit/explicit casting (return type: floating point).

en.cppreference.com/w/cpp/numeric/math

<limits> Numerical Limits

Get numeric limits of a given type:

<limits> C++11

```
T numeric_limits<T>:: max() // returns the maximum finite value  
// value representable
```

```
T numeric_limits<T>:: min() // returns the minimum finite value  
// value representable
```

```
T numeric_limits<T>:: lowest() // returns the lowest finite  
// value representable
```

<numeric> Mathematical Constants

<numeric> C++20

The header provides numeric constants

- `e` Euler number e
- `pi` π
- `phi` Golden ratio $\frac{1+\sqrt{5}}{2}$
- `sqrt2` $\sqrt{2}$

Integer Division

Integer ceiling division and rounded division:

- **Ceiling Division:** $\left\lceil \frac{\text{value}}{\text{div}} \right\rceil$

```
unsigned ceil_div(unsigned value, unsigned div) {
    return (value + div - 1) / div;
} // note: may overflow
```

- **Rounded Division:** $\left\lfloor \frac{\text{value}}{\text{div}} + \frac{1}{2} \right\rfloor$

```
unsigned round_div(unsigned value, unsigned div) {
    return (value + div / 2) / div;
} // note: may overflow
```

Note: do not use floating-point conversion (see Basic Concept I)

`std::string`

std::string is a wrapper of character sequences

More flexible and safer than raw char array but can be slower

```
#include <string>

int main() {
    std::string a;           // empty string
    std::string b("first");

    using namespace std::string_literals; // C++14
    std::string c = "second"s;           // C++14
}
```

- `empty()` returns `true` if the string is empty, `false` otherwise
- `size()` returns the number of characters in the string
- `find(string)` returns the position of the first substring equal to the given character sequence or `npos` if no substring is found
- `rfind(string)` returns the position of the last substring equal to the given character sequence or `npos` if no substring is found
- `find_first_of(char_seq)` returns the position of the first character equal to one of the characters in the given character sequence or `npos` if no characters is found
- `find_last_of(char_seq)` returns the position of the last character equal to one of the characters in the given character sequence or `npos` if no characters is found

`npos` special value returned by string methods

- `new_string substr(start_pos)`
returns a substring [start_pos, end]
`new_string substr(start_pos, count)`
returns a substring [start_pos, start_pos + count)
- `clear()` removes all characters from the string
- `erase(pos)` removes the character at position
`erase(start_pos, count)`
removes the characters at positions [start_pos, start_pos + count)
- `replace(start_pos, count, new_string)`
replaces the part of the string indicated by [start_pos, start_pos + count) with `new_string`
- `c_str()`
returns a pointer to the raw char sequence

- **access specified character** `string1[i]`
- **string copy** `string1 = string2`
- **string compare** `string1 == string2`
works also with `!=,<,<,>,>`
- **concatenate two strings** `string_concat = string1 + string2`
- **append characters to the end** `string1 += string2`

Conversion from/to Numeric Values

Converts a string to a numeric value C++11:

- `stoi(string)` string to signed integer
- `stol(string)` string to long signed integer
- `stoul(string)` string to long unsigned integer
- `stoull(string)` string to long long unsigned integer
- `stof(string)` string to floating point value (float)
- `stod(string)` string to floating point value (double)
- `stold(string)` string to floating point value (long double)
- C++17 `std::from_chars(start, end, result, base)` fast string conversion (no allocation, no exception)

Converts a numeric value to a string:

- C++11 `to_string(numeric_value)` numeric value to string

Examples

```
std::string str("si vis pacem para bellum");
cout << str.size();      // print 24
cout << str.find("vis"); // print 3
cout << str.find_last_of("bla"); // print 21, 'l' found

cout << str.substr(7, 5); // print "pacem", pos=7 and count=5
cout << str[1];          // print 'i'
cout << (str == "vis"); // print false
cout << (str < "z");    // print true
const char* raw_str = str.c_str();

cout << string("a") + "b"; // print "ab"
cout << string("ab").erase(0); // print 'b'

char*      str2 = "34";
int       a     = std::stoi(str2);   // a = 34;
std::string str3 = std::to_string(a); // str3 = "34"
```

Tips

- Conversion from integer to char letter (e.g. $3 \rightarrow 'C'$):

```
static_cast<char>('A' + value)
```

$\text{value} \in [0, 26]$ (English alphabet)

- Conversion from char to integer (e.g. $'C' \rightarrow 3$): `value - 'A'`

$\text{value} \in [0, 26]$

- Conversion from digit to char number (e.g. $3 \rightarrow '3'$):

```
static_cast<char>('0' + value)
```

$\text{value} \in [0, 9]$

- char to string `std::string(1, char_value)`

C++17 `std::string_view` describes a minimum common interface to interact with string data:

- `const std::string&`
- `const char*`

The purpose of `std::string_view` is to avoid copying data which is already owned by the original object

```
#include <string>
#include <string_view>

int main() {
    std::string str = "abc"; // new memory allocation + copy
    std::string_view = "abc"; // only the reference
}
```

std::string_view provides similar functionalities of std::string

```
#include <iostream>
#include <string>
#include <string_view>

void string_op1(const std::string& str) {}
void string_op2(std::string_view str) {}

int main() {
    string_op1("abcdef"); // allocation + copy
    string_op2("abcdef"); // reference

    const char* str1 = "abcdef";
    std::string str2("abcdef");      // allocation + copy
    std::cout << str2.substr(0, 3); // print "abc"

    std::string_view str3(str1);    // reference
    std::cout << str3.substr(0, 3); // print "abc"
}
```

std::string_view supports constexpr constructor and methods

```
constexpr std::string_view str1("abc");
constexpr std::string_view str2 = "abc";

constexpr char c = str1[0];           // 'a'
constexpr bool b = (str1 == str2); // 'true'

constexpr int size = str1.size();           // '3'
constexpr std::string_view str3 = str1.substr(0, 2); // "ab"

constexpr int pos = str1.find("bc");           // '1'
```

`printf` functions: no automatic type deduction, error prone, not extensible

`stream` objects: very verbose, hard to optimize

C++20 `std::format` provides python style formatting:

- Type-safe
- Support positional arguments
- Extensible (support user-defined types)
- Return a `std::string`

Integer formatting

```
std::format("{}", 3);    // "3"  
std::format("{:b}", 3); // "101"
```

Floating point formatting

```
std::format("{:.1f}", 3.273); // "3.1"
```

Alignment

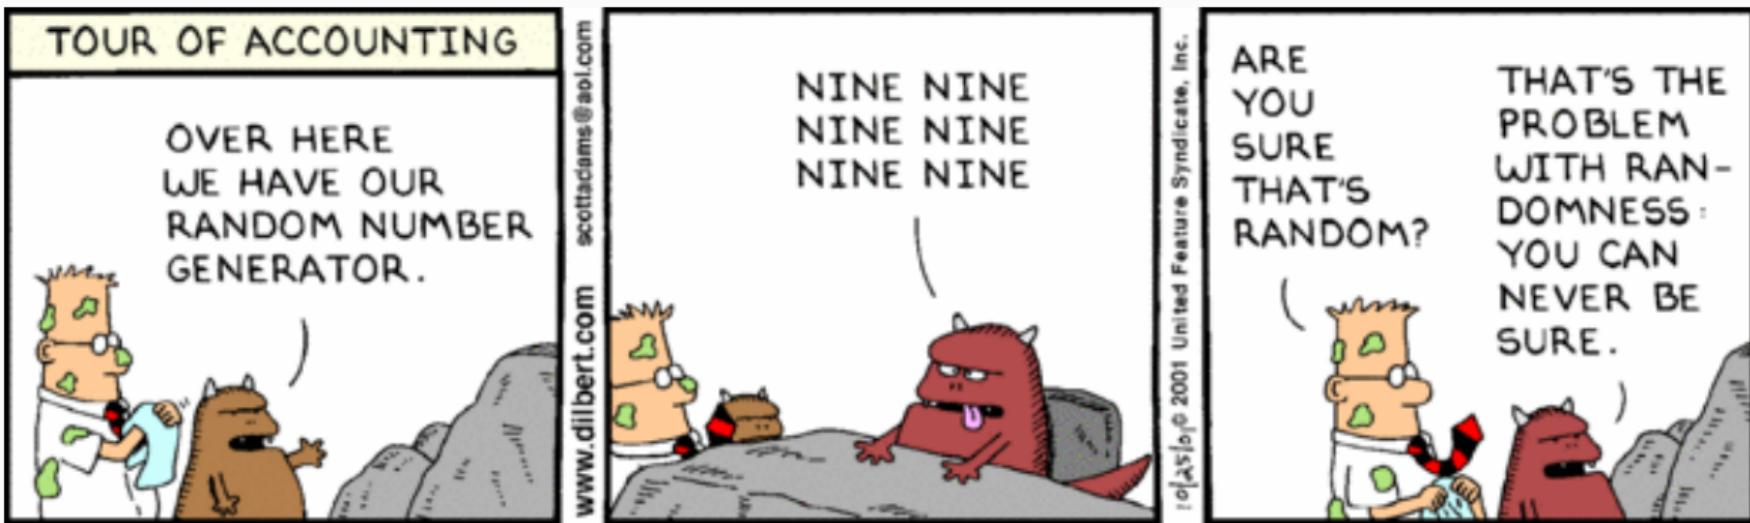

```
std::format("{:>6}", 3.27); // " 3.27"  
std::format("{:<6}", 3.27); // "3.27  "
```

Argument reordering

```
std::format("{1} - {0}", 1, 3); // "3 - 1"
```

Random Number

Random Number

"Random numbers should not be generated with a method chosen at random"

Basic Concepts

- A **pseudorandom (PRNG)** *sequence of numbers* satisfies most of the statistical properties of a truly random sequence but is generated by a *deterministic* algorithm (deterministic finite-state machine)
- A **quasirandom** *sequence of n -dimensional points* is generated by a *deterministic* algorithm designed to fill an n -dimensional space evenly
- The **state** of a PRNG describes the status of the generator (the values of its variables), namely where the system is after a certain amount of transitions
- The **seed** is a value that initializes the *starting state* of a PRNG. The same seed always produces the same sequence of results
- The **offset** of a sequence is used to skip ahead in the sequence
- PRNGs produce **uniformly distributed** values. PRNGs can also generate values according to a probability function (binomial, normal, etc.)

The problem:

C `rand()` function produces poor quality random numbers

- C++14 discourage the use of `rand()` and `srand()`

C++11 introduces pseudo random number generation (PRNG) facilities to produce random numbers by using combinations of generators and distributions

A random generator requires four steps:

(1) **Select the seed**

(2) **Define the random engine**

```
<type_of_random_engine> generator(seed)
```

(3) **Define the distribution**

```
<type_of_distribution> distribution(range_start, range_end)
```

(4) **Produce the random number**

```
distribution(generator)
```

Simplest example:

```
#include <iostream>
#include <random>

int main() {
    unsigned seed = ...;
    std::default_random_engine generator(seed);
    std::uniform_int_distribution<int> distribution(0, 9);

    std::cout << distribution(generator);
        // first random number
    std::cout << distribution(generator);
}                                // second random number
```

It generates two random integer numbers in the range [0, 9] by using the default random engine

Given a **seed**, the generator produces always the **same sequence**

The seed could be selected randomly by using the current time:

```
#include <random>
#include <chrono>
int main() {
    unsigned seed = std::chrono::system_clock::now()
                    .time_since_epoch().count();
    std::default_random_engine generator(seed);
}
```

`chrono::system_clock::now()` returns an object representing the current point in time

`.time_since_epoch().count()` returns the count of ticks that have elapsed since January 1, 1970
(midnight UTC/GMT)

Problem: Consecutive calls return *very similar* seeds

A **random device** `std::random_device` is a uniformly distributed integer generator that produces non-deterministic random numbers (e.g. from a hardware device)

Note: Not all systems provide a random device

```
#include <random>

int main() {
    std::random_device rnd_device;
    std::default_random_engine generator(rnd_device());
}
```

`std::seed_seq` consumes a sequence of integer-valued data and produces a number of unsigned integer values in the range $[0, 2^{32} - 1]$. The produced values are distributed over the entire 32-bit range even if the consumed values are close

```
#include <random>
#include <chrono>

int main() {
    unsigned seed1 = std::chrono::system_clock::now()
                    .time_since_epoch().count();
    unsigned seed2 = seed1 + 1000;

    std::seed_seq seq1{ seed1, seed2 };
    std::default_random_engine generator1(seq);

    std::random_device rnd;
    std::default_random_engine generator1(rnd());
}
```

PRNG Period and Quality

PRNG Period

The **period** (or **cycle length**) of a PRNG is the length of the sequence of numbers that the PRNG generates before repeating

PRNG Quality

(*informal*) If it is hard to distinguish a generator output from *truly* random sequences, we call it a **high quality** generator. Otherwise, we call it **low quality** generator

Generator	Quality	Period	Randomness
Linear Congruential	Poor	$2^{31} \approx 10^9$	Statistical tests
Mersenne Twister 32/64-bit	High	10^{6000}	Statistical tests
Subtract-with-carry 24/48-bit	Highest	10^{171}	Mathematically proven

Random Engines

- **Linear congruential (LF)**

The simplest generator engine. Modulo-based algorithm:

$$x_{i+1} = (\alpha x_i + c) \bmod m \text{ where } \alpha, c, m \text{ are implementation defined}$$

C++ Generators: `std::minstd_rand` , `std::minstd_rand0` ,
`std::knuth_b`

- **Mersenne Twister (M. Matsumoto and T. Nishimura, 1997)**

Fast generation of high-quality pseudorandom number. It relies on Mersenne prime number.
(used as default random generator in linux)

C++ Generators: `std::mt19937` , `std::mt19937_64`

- **Subtract-with-carry (LF) (G. Marsaglia and A. Zaman, 1991)**

Pseudo-random generation based on Lagged Fibonacci algorithm (used for example by
physicists at CERN)

C++ Generators: `std::ranlux24_base` , `std::ranlux48_base` , `std::ranlux24` , `std::ranlux48`

Statistical Tests

The table shows after how many iterations the generator fails the statistical tests

Generator	256M	512M	1G	2G	4G	8G	16G	32G	64G	128G	256G	512G	1T
ranlux24_base	✗	✗	✗	✗	✗	✗	✗	✗	✗	✗	✗	✗	✗
ranlux48_base	✗	✗	✗	✗	✗	✗	✗	✗	✗	✗	✗	✗	✗
minstd_rand	✗	✗	✗	✗	✗	✗	✗	✗	✗	✗	✗	✗	✗
minstd_rand0	✗	✗	✗	✗	✗	✗	✗	✗	✗	✗	✗	✗	✗
knuth_b	✓	✓	✗	✗	✗	✗	✗	✗	✗	✗	✗	✗	✗
mt19937	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✗	✗
mt19937_64	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✗
ranlux24	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓
ranlux48	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓

Space and Performance

Generator	Predictability	State	Performance
Linear Congruential	Trivial	4–8 B	Fast
Knuth	Trivial	1 KB	Fast
Mersenne Twister	Trivial	2 KB	Good
randlux_base	Trivial	8–16 B	Slow
randlux	Unknown?	~120 B	Super slow

Distribution

- **Uniform distribution** `uniform_int_distribution<T>(range_start, range_end)`
where T is integral type
`uniform_real_distribution<T>(range_start, range_end)` where T is floating point type
- **Normal distribution** $P(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$
`normal_distribution<T>(mean, std_dev)`
where T is floating point type
- **Exponential distribution** $P(x, \lambda) = \lambda e^{-\lambda x}$
`exponential_distribution<T>(lambda)`
where T is floating point type

Examples

```
unsigned seed = ...  
  
// Original linear congruential  
minstd_rand0 lc1_generator(seed);  
// Linear congruential (better tuning)  
minstd_rand lc2_generator(seed);  
// Standard mersenne twister (64-bit)  
mt19937_64 mt64_generator(seed);  
// Subtract-with-carry (48-bit)  
ranlux48_base swc48_generator(seed);  
  
uniform_int_distribution<int> int_distribution(0, 10);  
uniform_real_distribution<float> real_distribution(-3.0f, 4.0f);  
exponential_distribution<float> exp_distribution(3.5f);  
normal_distribution<double> norm_distribution(5.0, 2.0);
```

Performance Comparison

The **quasi-random** numbers have the low-discrepancy property that is a measure of *uniformity for the distribution* of the point for the multi-dimensional case

- Quasi-random sequence, in comparison to pseudo-random sequence, distributes evenly, namely this leads to spread the number over the entire region
- The concept of low-discrepancy is associated with the property that the successive numbers are added in a position as away as possible from the other numbers that is, avoiding *clustering* (grouping of numbers close to each other)

Pseudo-random vs. Quasi random

Time Measuring

Wall-Clock/Real time

It is the human perception of the passage of time from the start to the completion of a task

User/CPU time

The amount of time spent by the CPU to compute in user code

System time

The amount of time spent by the CPU to compute system calls (including I/O calls) executed into kernel code

Note: if the system workload (except the current program) is very low and the program uses only one thread then

$$\text{Wall-clock time} = \text{User time} + \text{System time}$$

:: gettimeofday() (linux, not portable)

```
#include <time.h>      // struct timeval
#include <sys/time.h> // gettimeofday()
#include <iostream>

int main() {
    struct timeval start, end; // timeval {second, microseconds}
    ::gettimeofday(&start, NULL);
    ... // code
    ::gettimeofday(&end, NULL);

    long start_time = start.tv_sec * 1000000 + start.tv_usec;
    long end_time   = end.tv_sec * 1000000 + end.tv_usec;
    std::cout << "Elapsed: " << end_time - start_time;
}

} // in microsec
```

Problems: not portable, the time is not monotonic increasing (timezone)

std::chrono C++11

```
#include <iostream>
#include <chrono>

int main() {
    auto start_time = std::chrono::system_clock::now();
    ... // code
    auto end_time   = std::chrono::system_clock::now();

    std::chrono::duration<double> diff = end_time - start_time;
    cout << "Elapsed: " << diff.count(); // in seconds
    cout << std::chrono::duration_cast<milli>(diff).count();
}
```

Problems: The time is not monotonic increasing (timezone)

An alternative of system_clock is steady_clock which ensures monotonic increasing time

std::clock

```
#include <iostream>
#include <chrono>

int main() {
    clock_t start_time = std::clock();
    ... // code
    clock_t end_time    = std::clock();

    float diff = static_cast<float>(end_time - start_time) / CLOCKS_PER_SEC;
    cout << "Elapsed: " << diff; // in seconds
}
```

```
#include <iostream>
#include <sys/types.h>

int main() {
    struct ::tms start_time, end_time;
    ::times(&start_time);
    ... // code
    ::times(&end_time);

    auto user_diff = end_time.tms_utime - start_time.tms_utime;
    auto sys_diff = end_time.tms_stime - start_time.tms_stime;
    float user     = static_cast<float>(user_diff) / ::sysconf(_SC_CLK_TCK);
    float sys      = static_cast<float>(sys_diff)   / ::sysconf(_SC_CLK_TCK);
    std::cout << "user time: "   << user;   // in seconds
    std::cout << "system time: " << sys;    // in seconds
}
```

Std Template Classes

<utility>

`std::pair` class couples together a pair of values, which may be of different types

Construct a `std::pair`

- `std::pair<T1, T2> pair(value1, value2)`
- `std::pair<T1, T2> pair = {value1, value2}`
- `auto pair = std::make_pair(value1, value2)`

Data members:

- `first` access first field
- `second` access second field

Methods:

- comparison `==, <, >, ≥, ≤`
- `swap std::swap`

```
#include <utility>
#include <iostream>
int main() {
    using namespace std;
    std::pair<int, std::string> pair1(3, "abc");
    std::pair<int, std::string> pair2 = { 4, "zzz" };
    auto pair3 = std::make_pair(3, "hgt");

    cout << pair1.first; // print 3
    cout << pair1.second; // print "abc"

    swap(pair1, pair2);
    cout << pair2.first; // print "zzz"
    cout << pair2.second; // print 4

    cout << (pair1 > pair2); // print 1
}
```

<tuple>

`std::tuple` is a fixed-size collection of heterogeneous values. It is a generalization of `std::pair`. It allows any number of values

Construct a `std::tuple` (of size 3)

- `std::tuple<T1, T2, T3> tuple(value1, value2, value3)`
- `std::tuple<T1, T2, T3> tuple = {value1, value2, value3}`
- `auto tuple = std::make_tuple(value1, value2, value3)`

Data members:

`std::get<I>(tuple)` returns the *i*-th value of the tuple

Methods:

- comparison `==, <, >, ≥, ≤`
- `swap std::swap`

- `auto t3 = std::tuple_cat(t1, t2)`
concatenate two tuples
- `const int size = std::tuple_size<TupleT>::value`
returns the number of elements in a tuple at compile-time
- `using T = typename std::tuple_element<TupleT>::type` obtains the type of the specified element
- `std::tie(value1, value2, value3) = tuple`
creates a tuple of references to its arguments
- `std::ignore`
an object of unspecified type such that any value can be assigned to it with no effect

```
#include <tuple>
#include <iostream>
std::tuple<int, float, char> f() { return {7, 0.1f, 'a'}; }

int main() {
    std::tuple<int, char, float> tuple1(3, 'c', 2.2f);
    auto tuple2 = std::make_tuple(2, 'd', 1.5f);

    std::cout << std::get<0>(tuple1); // print 3
    std::cout << std::get<1>(tuple1); // print 'c'
    std::cout << std::get<2>(tuple1); // print 2.2f
    std::cout << (tuple1 > tuple2); // print true

    auto concat = std::tuple_cat(tuple1, tuple2);
    std::cout << std::tuple_size<decltype(concat)>::value; // print 6

    using T = std::tuple_element<4, decltype(concat)>::type; // T is int
    int value1; float value2;
    std::tie(value1, value2, std::ignore) = f();
}
```

<variant> C++17

`std::variant` represents a **type-safe union** as the corresponding objects know which type is currently being held

It can be indexed by:

- `std::get<index>(variant)` an integer
- `std::get<type>(variant)` a type

```
#include <variant>

int main() {
    std::variant<int, float, bool> v(3.3f);
    int x = std::get<0>(v);      // return integer value
    bool y = std::get<bool>(v); // return bool value
    // std::get<0>(v) = 2.0f;     // run-time exception!!
}
```

Another useful method is `index()` which returns the position of the type currently held by the variant

```
#include <variant>
using namespace std;

int main() {
    std::variant<int, float, bool> v(3.3f);

    cout << v.index(); // return 1

    std::get<bool>(v) = true
    cout << v.index(); // return 2
}
```

It is also possible to query the index at run-time depending on the type currently being held by providing a **visitor**

```
#include <iostream>
#include <variant>
struct Visitor {
    void operator()(int& value)    { value *= 2; }

    void operator()(float& value) { value += 3.0f; } // <-- here

    void operator()(bool& value)   { value = true; }
};

int main() {
    std::variant<int, float, bool> v(3.3f);

    std::visit(v, Visitor{});

    std::cout << std::get<float>(v); // 6.3f
}
```

<optional> C++17

`std::optional` provides facilities to represent potential “no value” states

As an example, it can be used for representing the state when an element is not found in a set

```
#include <iostream>
#include <optional>

std::optional<std::string> find(const char* set, char value) {
    for (int i = 0; i < 10; i++) {
        if (set[i] == value)
            return i;
    }
    return {}; // std::nullopt;
}
```

```
#include <iostream>
using namespace std;

int main() {
    char set[] = "sdfslgfsgd";
    auto x      = find(set, 'a'); // 'a' is not present
    if (!x)
        cout << "not found";
    if (!x.has_value())
        cout << "not found";

    auto y = find(set, 'l');
    cout << *y << " " << y.value(); // print '4' '4'

    x.value_or(-1); // returns '-1'
    y.value_or(-1); // returns '4'
}
```

std::any

<any> C++17

std::any holds arbitrary values and provides **type-safety**

```
#include <any>
#include <iostream>
using namespace std;
int main() {
    std::any var = 1;           // int
    cout << var.type().name(); // print 'i'

    cout << std::any_cast<int>(var);
// cout << std::any_cast<float>(var); // exception!!

    var = 3.14; // double
    cout << std::any_cast<double>(var);

    var.reset();
    cout << var.has_value(); // print 'false'
}
```

Filesystem Library

Filesystem Library

C++17 introduces abstractions and facilities for performing operations on file systems and their components, such as **paths**, **files**, and **directories**

- Follow the Boost filesystem library
- Based on POSIX
- Fully-supported from clang 7, gcc 8, etc.
- Work on Windows, Linux, Android, etc.

Basic concepts

- **file**: a file system object that holds data
 - **directory** a container of directory entries
 - **hard link** associates a name with an existing file
 - **symbolic link** associates a name with a path
 - **regular file** a file that is not one of the other file types
- **file name**: a string of characters that names a file. Names `.` (dot) and `..` (dot-dot) have special meaning at library level
- **path**: sequence of elements that identifies a file
 - **absolute path**: a path that unambiguously identifies the location of a file
 - **canonical path**: an absolute path that includes no symlinks, `.` or `..` elements
 - **relative path**: a path that identifies a file relative to some location on the file system

path Object

A `path` object stores the pathname in native form

```
#include <iostream>
#include <filesystem> // required

int main() {
    namespace fs = std::filesystem;

    fs::path p1 = "/usr/lib/sendmail.cf"; // portable format
    fs::path p2 = "C:\\users\\abcdef\\\"; // native format

    std::cout << "p1: " << p1;           // /usr/lib/sendmail.cf
    std::cout << "p2: " << p2;           // C:\users\abcdef\

    std::cout << "p3: " << p2 + "xyz\\\"; // C:\users\abcdef\xyz\
}
```

path Methods

Decomposition (member) methods:

- Return root-name of the path
`root_name()`
- Return path relative to the root path
`relative_path()`
- Return the path of the parent path
`parent_path()`
- Return the filename path component
`filename()`
- Return the file extension path component
`extension()`

Filesystem Methods - Query

- Check if a file or path exists

```
exists(path)
```

- Return the file size

```
file_size(path)
```

- Check if a file is a directory

```
is_directory(path)
```

- Check if a file (or directory) is empty

```
is_empty(path)
```

- Check if a file is a regular file

```
is_regular_file(path)
```

- Returns the current path

```
current_path()
```

Directory Iterators

Iterate over files of a directory (recursively/non-recursively)

```
#include <iostream>
#include <filesystem>

int main() {
    namespace fs = std::filesystem;

    for(auto& path : fs::directory_iterator("/usr/tmp/"))
        std::cout << path << '\n';

    for(auto& path : fs::recursive_directory_iterator("/usr/tmp/"))
        std::cout << path << '\n';
}
```

Filesystem Methods - Modify

- **Copy files or directories**

```
copy(path1, path2)
```

- **Copy files**

```
copy_file(src_path, src_path, [fs::copy_options::recursive])
```

- **Create new directory**

```
create_directory(path)
```

- **Remove a file or empty directory**

```
remove(path)
```

- **Remove a file or directory and all its contents, recursively**

```
remove_all(path)
```

- **Rename a file or directory**

```
rename(old_path, new_path)
```

Examples

```
#include <iostream>
#include <filesystem> // required

int main() {
    namespace fs = std::filesystem;
    fs::path p1 = "/usr/tmp/my_file.txt";

    std::cout << p1.exists();           // true
    std::cout << p1.parent_path();     // "/usr/tmp/"
    std::cout << p1.filename();        // "my_file"
    std::cout << p1.extension();       // "txt"
    std::cout << p1.is_directory();    // false
    std::cout << p1.is_regular_file(); // true

    fs::create_directory("/my_dir/");
    fs::copy(p1.parent_path(), "/my_dir/", fs::copy_options::recursive);
    fs::copy_file(p1, "/my_dir/my_file2.txt");
    fs::remove(p1);
    fs::remove_all(p1.parent_path());
}
```
