

# Modern C++ Programming

## 15. ADVANCED TOPICS

---

*Federico Busato*

University of Verona, Dept. of Computer Science  
2021, v3.02

## 1 Move Semantic

- lvalues and rvalues references
- Move Semantic
- Compiler Implicitly Declared
- `std::move`

## 2 Universal Reference and Perfect Forwarding

- Universal Reference
- Reference Collapsing Rules
- Perfect Forwarding

## **3** Value Categories

## **4** Copy Elision and RVO

## **5** Type Deduction

- Pass-by-Reference
- Pass-by-Pointer
- Pass-by-Value

## **6** `const` Correctness

## 7 C++ Idioms

- Rule of Zero/Three/Five
- Singleton
- PIMPL
- CRTP
- Template Virtual Functions

## 8 Smart pointers

- `std::unique_ptr`
- `std::shared_ptr`
- `std::weak_ptr`

## 9 Concurrency

- Thread Methods
- Mutex
- Atomic
- Task-based parallelism

# Move Semantic

---

***Move semantics refers in transferring ownership of resources from one object to another***

Differently from *copy semantic*, *move semantic* does not duplicate the original resource

In C++ every expression is either an **rvalue** or an **lvalue**

- a **lvalue** (left) represents an expression that occupies some identifiable location in memory
- a **rvalue** (right) is an expression that does not represent an object occupying some identifiable location in memory

```
int x = 5;           // "x" is a lvalue, "5" is an rvalue
int y = 10;         // "y" is a lvalue

int z = (x * y);    // "z" is an lvalue, (x * y) is an rvalue
```

C++11 introduces a new kind of *reference* called **rvalue reference** `X&&`

- An **rvalue reference** only binds to an **rvalue**, that is a temporary
- An **lvalue reference** only binds to an **lvalue**
- A **const lvalue reference** binds to both **lvalue** and **rvalue**

```
int      x = 5;          // "x" is an lvalue
int&     r1 = x;        // "r1" is an lvalue reference
// int&  r2 = 5;        // error, "5" is an rvalue
const int& cr = (x * y); // "cr" is an const lvalue reference

int&&    rv = (x * y);  // "rv" is an rvalue
// int&&  rv1 = x;      // error, "x" is NOT an rvalue
```

```
struct A {};  
  
void f(A& a) {}           // lvalue reference  
  
void g(const A& a) {}    // const lvalue reference  
  
void h(A&& a) {}         // rvalue reference  
  
int main() {  
    A a;  
    f(a); // ok, f() can modify "a"  
    g(a); // ok, f() cannot modify "a"  
    // h(a); // compile error f() does not accept lvalues  
  
    // f(A{}); // compile error f() does not accept rvalues  
    g(A{}); // ok, f() cannot modify the object A{}  
    h(A{}); // ok, f() can modify the object A{}  
}
```

```
#include <algorithm>

class Array { // Array Wrapper
public:
    Array() = default;

    Array(int size) : _size{size}, _array{new int[size]} {}

    Array(const Array& obj) : _size{obj._size} {
        // EXPENSIVE COPY
        std::copy(obj._array, obj._array + _size, _array);
    }

    ~Array() { delete[] _array; }
private:
    int _size;
    int* _array;
};
```

```
#include <vector>

int main() {
    std::vector<Array> vector;
    vector.push_back( Array{1000} ); // expensive copy
}
```

**Before C++11:** `Array{1000}` is created, passed by const-reference, copied, and then destroyed

Note: `Array{1000}` is no more used outside `push_back`

**After C++11:** `Array{1000}` is created, and moved in `vector` (fast!)

Class prototype with support for *move semantic*:

```
class X {  
public:  
    X();           // default constructor  
  
    X(const X& obj); // copy constructor  
  
    X(X&& obj);    // move constructor  
  
    X& operator=(const X& obj); // copy assign operator  
  
    X& operator=(X&& obj);    // move assign operator  
  
    ~X();           // destructor  
private:  
    Y _data;  
};
```

## Move constructor semantic

```
X(X&& obj);
```

- (1) *Shallow copy* of `obj` data members (in contrast to deep copy)
- (2) *Release* any `obj` resources and reset all data members (pointer to `nullptr`, size to 0, etc.)

## Move assignment semantic

```
X& operator=(X&& obj);
```

- (1) *Release* any resources of `this`
- (2) *Shallow copy* of `obj` data members (in contrast to deep copy)
- (3) *Release* any `obj` resources and reset all data members (pointer to `nullptr`, size to 0, etc.)
- (4) Return `*this`

## Move constructor

```
Array(Array&& obj) {  
    _size      = obj._size; // (1) shallow copy  
    _array     = obj._array; // (1) shallow copy  
    obj._size  = 0;          // (2) release obj (no more valid)  
    obj._array = nullptr;   // (2) release obj  
}
```

## Move assignment

```
Array& operator=(Array&& obj) {  
    delete[] _array; // (1) release this  
    _size = obj._size; // (2) shallow copy  
    _array = obj._array; // (2) shallow copy  
    delete[] obj._array; // (3) release obj  
    obj._size = 0; // (3) release obj  
    return *this; // (4) return *this  
}
```

## Special Members

compiler implicitly declares

	default constructor	destructor	copy constructor	copy assignment	move constructor	move assignment
Nothing	defaulted	defaulted	defaulted	defaulted	defaulted	defaulted
Any constructor	not declared	defaulted	defaulted	defaulted	defaulted	defaulted
default constructor	user declared	defaulted	defaulted	defaulted	defaulted	defaulted
destructor	defaulted	user declared	defaulted	defaulted	not declared	not declared
copy constructor	not declared	defaulted	user declared	defaulted	not declared	not declared
copy assignment	defaulted	defaulted	defaulted	user declared	not declared	not declared
move constructor	not declared	defaulted	deleted	deleted	user declared	not declared
move assignment	defaulted	defaulted	deleted	deleted	not declared	user declared

**C++11** provides the method `std::move` ( `<utility>` ) to indicate that an object may be “moved from”

It allows to efficient transfer resources from an object to another one

```
#include <vector>

int main() {
    std::vector<Array> vector;
    vector.push_back( Array{1000} );    // call move constructor
                                        // (C++11)

    Array arr{1000};
    vector.push_back( arr );            // call copy constructor
                                        // (also in C++11)

    vector.push_back( std::move(arr) ); // call move constructor
}
```

# Universal Reference and Perfect Forwarding

---

The `&&` syntax has two different meanings depending on the context it is used

- **rvalue reference**
- Either **rvalue reference** or **lvalue reference**  
(*universal reference*, cit. Scott Meyers)

**“Universal references”** (also called *forwarding references*) are **rvalues** that appear in a type-deducing context

```
void f1(int&& t) {} // rvalue reference

template<typename T>
void f2(T&& t) {} // universal reference

int&& v1 = ...; // rvalue reference
auto&& v2 = ...; // universal reference
```

```
struct A {};  
void f1(A&& a) {} // rvalue only  
  
template<typename T>  
void f2(T&& t) {} // universal reference  
  
int main() {  
    A a;  
    f1(A{}); // ok  
    // f1(a); // compile error (only rvalue)  
    f2(A{}); // universal reference  
    f2(a); // universal reference  
  
    A&& a2 = A{}; // ok  
    // A&& a3 = a; // compile error (only rvalue)  
    auto&& a4 = A{}; // universal reference  
    auto&& a5 = a; // universal reference  
}
```

## Universal Reference - Misleading Cases

```
template<typename T>  
void f(const T&&) {}           // rvalue reference (const)  
  
template<typename T>  
void f(std::vector<T>&&) {}    // rvalue reference  
  
const auto&& v = ...;        // const lvalue reference
```

## Reference Collapsing Rules

Before C++11 (C++98, C++03), it was not allowed to take a reference to a reference ( `A&&` causes a compile error)

C++11, by contrast, introduces the following **reference collapsing rules**:

```
template<typename T>
void f(T&) {} // compile error in C++98/03
              // (with gcc), no errors in C++11
int a = 3;    // (and clang with C++98/03)
f<int&&>(a);
```

Type	Reference		Result
A&	&	→	A&
A&	&&	→	A&
A&&	&	→	A&
A&&	&&	→	A&&

# Perfect Forwarding

*Perfect forwarding* allows preserving argument *value category* and `const/volatile` modifiers

`std::forward` ( `<utility>` ) forwards the argument to another function with the *value category* it had when passed to the calling function (*perfect forwarding*)

```
#include <utility> // std::forward
template<typename T> void f(T& t) { cout << "lvalue"; }
template<typename T> void f(T&& t) { cout << "rvalue"; }

template<typename T> void g1(T&& obj) { f(obj); } // call only f(T&)
template<typename T> void g2(T&& obj) { f(std::forward<T>(obj)); }

struct A{};
f ( A{10} ); // print "rvalue"
g1( A{10} ); // print "lvalue!!"
g2( A{10} ); // print "lvalue"
```

# Value Categories

---

## Taxonomy (simplified)

Every expression is either an **rvalue** or an **lvalue**

- An **lvalue** (*left* value of an assignment for historical reason or *locator* value) represents an expression that occupies an *identity*, namely a memory location (it has an address)
- **rvalues** (*right* value of an assignment) are defined by exclusion
- An **rvalue** is movable; an **lvalue** is not

**glvalue** (*generalized lvalue*) is an expression that has an identity

**lvalue** is a **glvalue** but it is not movable (it is not an **xvalue**).

An *named rvalue reference* is a **lvalue**

**prvalue** (*pure rvalue*) doesn't have identity, but is movable. It is an expression whose evaluation initializes an object or computes the value of an operand of an operator

**xvalue** (*eXpiring*) has an identity and it is movable. It is a **glvalue** that denotes an object whose resources can be reused. An *unnamed rvalue reference* is a **xvalue**

**rvalue** is movable. It is a **prvalue** or an **xvalue**

# Examples

```
struct A {
    int x;
};

void f(A&&) {}
A&& g();
//-----

int a = 4;           // "a" is an lvalue, "4" is a prvalue
f(A{4});            // "A{4}" is a prvalue

A&& b = A{3};       // "A&& b" is a named rvalue reference → lvalue

A c{4};
f(std::move(c));   // "std::move(c)" is a xvalue
f(A{}.x);          // "A{}.x" is a xvalue
g();              // "g()" is a xvalue
```

# Copy Elision and RVO

---

**Copy elision** is a compiler optimization technique that eliminates unnecessary copying/moving of objects (it is defined in the C++ standard)

A compiler avoids omitting copy/move operations in these cases:

- **RVO (Return Value Optimization)** means the compiler is allowed to avoid creating *temporary* objects for return values
- **NRVO (Named Return Value Optimization)** means the compiler is allowed to return an object (with automatic storage duration) without invokes copy/move constructors

```
class Array {  
public:  
    Array(const Array&) {  
        cout << "copy constructor";  
    }  
  
    Array(Array&&) {  
        cout << "move constructor";  
    }  
  
    Array& operator=(const Array&) {  
        cout << "copy assignment";  
    }  
  
    Array& operator=(Array&&) {  
        cout << "move assignment";  
    }  
};
```

```
Array f1() {  
    return Array{10}; // RVO  
}  
  
Array f2(bool b) {  
    return b ? Array{10} : Array{5}; // RVO  
}  
  
Array f3() {  
    Array arr{10};  
    return arr; // NRVO  
}
```

```
Array f4(bool b) {  
    Array arr1{10}, arr2{5};  
    return b ? arr1 : arr2; // copy constructor  
}  
  
Array f5() {  
    Array arr{10};  
    return std::move(arr); // move constructor  
}  
  
Array&& f6() {  
    Array arr{10};  
    return std::move(arr); // move constructor  
}
```

```
Array f7() {  
    static Array arr{10};  
    return arr;          // copy constructor  
}  
  
int main() {  
    Array arr = f1();    // ok RVO  
    arr      = f1();    // move operator= (no RVO)  
}
```

## Guaranteed Copy Elision (C++17)

The following code does not compile on pre-C++17 standard

```
struct A {  
    A() {}  
    A(const A&) = delete;  
    A(const A&&) = delete;  
};  
  
A f() { return A{}; }  
  
int main() {  
    A a = f(); // only on >= C++17  
}
```

# Type Deduction

---

**When you call a template function, you may omit any template argument that the compiler can determine or deduce (inferred) by the usage and context of that template function call [IBM]**

- The compiler tries to deduce a template argument by comparing the type of the corresponding template parameter with the type of the argument used in the function call
- Similar to function default parameters, (any) template parameters can be deduced only if they are at end of the parameter list

Full Story: [IBM Knowledge Center](#)

## Example

```
template<typename T>
int add1(T a, T b) { return a + b; }

template<typename T, typename R>
int add2(T a, R b) { return a + b; }

template<typename T, int B>
int add3(T a) { return a + B; }

template<int B, typename T>
int add4(T a) { return a + B; }

int main() {
    add1(1, 2);           // ok
    // add1(1, 2u);       // the compiler expects the same type
    add2(1, 2u);         // ok (add2 is more generic)
    add3<int, 2>(1);     // "int" cannot be deduced
    add4<2>(1);          // ok
}
```

# Type Deduction - Pass-by-Reference

## Type deduction with references

```
template<typename T>
void f(T& a) {}

template<typename T>
void g(const T& a) {}

int main() {
    int      x = 3;
    int&     y = x;
    const int& z = x;
    f(x);    // T: int
    f(y);    // T: int
    f(z);    // T: const int // <-- !! it works...but it does not
    g(x);    // T: int      //      for "f(int& a)"!!
    g(y);    // T: int      //      (only non-const references)
    g(z);    // T: int      // <-- note the difference
}
```

## Type deduction with pointers

```
template<typename T>
void f(T* a) {}

template<typename T>
void g(const T* a) {}

int main() {
    int*      x = nullptr;
    const int* y = nullptr;
    auto      z = nullptr;
    f(x);     // T: int
    f(y);     // T: const int
    // f(z);  // compile error!! z: "nullptr_t != T*"
    g(x);     // T: int
    g(y);     // T: int  <-- note the difference
}
```

```
template<typename T>
void f(const T* a) {} // pointer to const-values

template<typename T>
void g(T* const a) {} // const pointer

int main() {
    int*          x = nullptr;
    const int*    y = nullptr;
    int* const    z = nullptr;
    const int* const w = nullptr;
    f(x);        // T: int
    f(y);        // T: int
    f(z);        // T: int
    // g(x);     // compile error!! objects pointed are not constant
    // g(y);     // the same (the pointer itself is constant)
    g(z);        // T: int
    g(w);        // T: const int
}
```

## Type deduction with values

```
template<typename T>
void f(T a) {}

template<typename T>
void g(const T a) {}

int main() {
    int      x = 2;
    const int y = 3;
    const int& z = y;
    f(x);    // T: int
    f(y);    // T: int!! (drop const)
    f(z);    // T: int!! (drop const&)
    g(x);    // T: int
    g(y);    // T: int
    g(z);    // T: int!! (drop reference)
}
```

```
template<typename T>
void f(T a) {}

int main() {
    int*      x = nullptr;
    const int* y = nullptr;
    int* const z = x;
    f(x);    // T = int*
    f(y);    // T = int* !! (const drop)
    f(z);    // T = int* const
}
```

# Type Deduction - Array

## Type deduction with arrays

```
template<typename T, int N>
void f(T (&array)[N]) {}    // type and size deduced

template<typename T>
void g(T array) {}

int main() {
    int    x[3] = {};
    const int y[3] = {};
    f(x);    // T: int, N: 3
    f(y);    // T: const int, N: 3
    g(x);    // T: int*
    g(y);    // T: const int*
}
```

```
template<typename T>
void add(T a, T b) {}

template<typename T, typename R>
void add(T a, R b) {}

template<typename T>
void add(T a, char b) {}

int main() {
    add(2, 3.0f);           // call add(T, R)
    // add(2, 3);          // error!! ambiguous match
    add<int>(2, 3);         // call add(T, T)
    add<int, int>(2, 3);    // call add(T, R)
    add(2, 'b');           // call add(T, char) -> nearest match
}
```

```
template<typename T, int N>
void f(T (&array)[N]) {}

template<typename T>
void f(T* array) {}

// template<typename T>
// void f(T array) {} // ambiguous

int main() {
    int x[3];
    f(x); // call f(T*) not f(T(&)[3]) !!
}
```

# const Correctness

---

**const correctness** refers to guarantee object/variable const consistency throughout its lifetime and ensuring safety from unintentional modifications

References:

- Isocpp: `const-correctness`
- GotW: `Const-Correctness`
- Abseil: `Meaningful 'const' in Function Declarations`
- `const is a contract`
- `Why const Doesn't Make C Code Faster`
- `Constant Optimization?`

- `const` entities do not change their values at run-time. This does not imply that they are evaluated at compile-time
- `const T*` is different from `T* const`. The first case means “*the content does not change*”, while the later “*the value of the pointer does not change*”
- Pass *by-const-value* and *by-value* parameters imply the *same* function signature
- Return *by-const-value* and *by-value* have different meaning
- `const_cast` can *break* const-correctness

**const** and member function:

- **const** member functions do not change the internal status of an object
- **mutable** fields can be modified by a **const** member function (they should not change the external view)

**const** and code optimization:

- **const** keyword purpose is for correctness (*type safety*) not for performance
- **const** may provide performance advantages in a few cases, e.g. non-trivial copy semantic

## Function Declarations Example

```
void f(int);  
void f(const int); // the declaration is exactly the same of  
                  // "void f(int)"!!  
  
void f(int*);  
void f(const int*); // different declaration  
  
void f(int&);  
void f(const int&); // different declaration
```

```
int          f();  
// const int f(); // compile error conflicting declaration
```

## const Return Example

```
const int const_value = 3;
```

```
const int& f2() { return const_value; }
```

```
// int&      f1() { return const_value; } // WRONG
```

```
int      f3() { return const_value; } // ok
```

```
struct A {
```

```
    void f()      { cout << "non-const"; }
```

```
    void f() const { cout << "const";     }
```

```
};
```

```
const A getA() { return A{}; }
```

```
auto a = getA(); // "a" is a copy
```

```
a.f();          // print "non-const"
```

```
getA().f();     // print "const"
```

## struct Example

```
struct A {           // struct A_const { // equal to "const A"
    int* ptr;        //     int* const ptr;
    int  value;      //     const int  value;
};                  // };

void f(A a) {
    a.value = 3;
    a.ptr[0] = 3;
}

void g(const A a) { // the same with g(const A&)
// a.value = 3; // compile error
    a.ptr[0] = 3; // "const" does not apply to "ptr" content!!
}

A a{new int[10]};
f(a);
g(a);
```

# Member Functions Example

```
struct A {  
    int value = 0;  
  
    int&      f1() { return value; }  
    const int& f2() { return value; }  
  
    // int&      f3() const { return value; } // WRONG  
    const int& f4() const { return value; }  
  
    int      f5() const { return value; } // ok  
    const int f6() const { return value; }  
};
```

# C++ Idioms

---

# Rule of Zero

The **Rule of Zero** is a rule of thumb for C++

Utilize the *value semantics* of existing types to avoid having to implement *custom* copy and move operations

**Note:** many classes (such as `std` classes) manage resources themselves and should not implement copy/move constructor and assignment operator

```
class X {
public:
    X(...); // constructor
           // NO need to define copy/move semantic
private:
    std::vector<int>    v; // instead raw allocation
    std::unique_ptr<int> p; // instead raw allocation
};
           // see smart pointer
```

## Rule of Three

The **Rule of Three** is a rule of thumb for C++(03)

If your class needs any of

- a copy constructor `X(const X&)`
- an assignment operator `X& operator=(const X&)`
- or a destructor `~X()`

defined explicitly, then it is likely to need all three of them

Some resources cannot or should not be copied. In this case, they should be declared as deleted

```
X(const X&) = delete  
X& operator=(const X&) = delete
```

## Rule of Five

The **Rule of Five** is a rule of thumb for C++11

If your class needs any of

- a copy constructor `X(const X&)`
- a move constructor `X(X&&)`
- an assignment operator `X& operator=(const X&)`
- an assignment operator `X& operator=(X&&)`
- or a destructor `~X()`

defined explicitly, then it is likely to need all five of them

# Singleton

**Singleton** is a software design pattern that restricts the instantiation of a class to one and only one object

A common application is for logging

```
class Singleton {
public:
    static Singleton& get_instance() { // note "static"
        static Singleton instance { ..init.. } ;
        return instance;    // destroyed at the end of the program
    }
                            // initiliazied at first use

    Singleton(const& Singleton)      = delete;
    void operator=(const& Singleton) = delete;
private:
    T _data;

    Singleton( ..args.. ) { // used in the initialization
        ...
    }
}
}
```

# PIMPL (Opaque Pointer)

**Pointer to IMPLementation (PIMPL)** idiom allow removing compilation dependencies on internal class implementations and improve compile times

header.hpp

```
class A {           // the class A is responsible to allocate
public:            // and deallocate Impl* ptr
    void f() {
        ptr->f();
    }
private:
    class Impl;    // forward declaration
    Impl* ptr;    // opaque pointer
};
```

source.cpp (Impl actual implementation)

```
class A::Impl {
public:
    void f() {
        ..do something..
    }
};
```

The **Curiously Recurring Template Pattern (CRTP)** is an idiom in which a class `X` derives from a class template instantiation using `X` itself as template argument

A common application is *static polymorphism*

```
template <class T>
struct Base {
    void my_method() {
        static_cast<T*>(this)->implementation();
    }
};

class Derived : public Base<Derived> {
    // void my_method() is inherited
private:
    void my_method_impl() { ... }
};
```

```
#include <iostream>

template <class T>
struct Writer {
    void write(const char* str) {
        static_cast<const T*>(this)->write_impl(str);
    }
};

class CerrWriter : public Writer<CerrWriter> {
private:
    void write_impl(const char* str) { std::cerr << str; }
};

class CoutWriter : public Writer<CoutWriter> {
private:
    void write_impl(const char* str) { std::cout << str; }
};

int main() {
    CoutWriter x;
    CerrWriter y;
    x.write("abc");
    y.write("abc");
}
```

**Virtual functions cannot have template arguments**, but they can be emulated by using the following pattern

```
class Base {
public:
    template<typename T>
    void method(T t);    // here we want to emulate a virtual method
}
```

```
class Base {
public:
    template<typename T>
    void method(T t) {
        v_method(t);    // call the actual implementation
    }
private:
    virtual void v_method(int t)    = 0; // v_method is valid only
    virtual void v_method(double t) = 0; // for "int" and "double"
};
```

Actual implementations for derived class `A` and `B`

```
class AImpl : public Base {
protected:
    template<typename T>
    void t_method(T t) { // template "method()" implementation for A
        std::cout << "A " << t << std::endl;
    }
};

class BImpl : public Base {
protected:
    template<typename T>
    void t_method(T t) { // template "method()" implementation for B
        std::cout << "B " << t << std::endl;
    }
};
```

```
template<class Impl>
class DerivedWrapper : public Impl {
private:
    void v_method(int t) {
        Impl::t_method(t);
    }
    void v_method(double t) {
        Impl::t_method(t);
    } // call the base method
};

using A = DerivedWrapper<AImpl>;
using B = DerivedWrapper<BImpl>;
```

```
int main(int argc, char* argv[]) {
    A a;
    B b;
    Base* base = nullptr;

    base = &a;
    base->method(1); // print "A 1"
    base->method(2.0); // print "A 2.0"

    base = &b;
    base->method(1); // print "B 1"
    base->method(2.0); // print "B 2.0"
}
```

method() calls v\_method() (pure virtual method of Base )  
v\_method() calls t\_method() (actual implementation)

# Smart pointers

---

# Smart Pointers

**Smart pointer** is a pointer-like type with some additional functionality, e.g. *automatic memory deallocation* (when the pointer is no longer in use, the memory it points to is deallocated), reference counting, etc.

C++11 provides three smart pointer types:

- `std::unique_ptr`
- `std::shared_ptr`
- `std::weak_ptr`

Smart pointers prevent most situations of memory leaks by making the memory deallocation automatic

Full Story: [embeddedartistry.com](http://embeddedartistry.com)

# Smart Pointers Benefits

- If a smart pointer goes *out-of-scope*, the appropriate method to release resources is called automatically. The memory is not left dangling
- Smart pointers will automatically be set to `nullptr` if not initialized or when memory has been released
- `std::shared_ptr` provides automatic reference count
- If a special `delete` function needs to be called, it will be specified in the pointer type and declaration, and will automatically be called on delete

std::unique\_ptr is used to manage any dynamically allocated object that is not shared by multiple objects

```
#include <iostream>
#include <memory>
struct A {
    A() { std::cout << "Constructor\n"; } // called when A()
    ~A() { std::cout << "Destructor\n"; } // called when u_ptr1,
}; // u_ptr2 are out-of-scope

int main() {
    auto raw_ptr = new A();
    std::unique_ptr<A> u_ptr1(new A());
    std::unique_ptr<A> u_ptr2(raw_ptr);
    // std::unique_ptr<A> u_ptr3(raw_ptr); // no error, but wrong!!
    //                                     // (same pointer)
    // u_ptr1 = &raw_ptr; // compile error (unique pointer)
    // u_ptr1 = u_ptr2; // compile error (unique pointer)
    u_ptr1 = std::move(u_ptr2); // delete u_ptr1;
} // u_ptr1 = u_ptr2;
// u_ptr2 = nullptr
```

## std::unique\_ptr methods

- `get()` returns the underlying pointer
- `operator*` `operator->` dereferences pointer to the managed object
- `operator[]` provides indexed access to the stored array (if it supports random access iterator)
- `release()` returns a pointer to the managed object and releases the ownership
- `reset(ptr)` replaces the managed object with ptr

Utility method: `std::make_unique<T>()` creates a unique pointer of a class T that manages a new object

```
#include <iostream>
#include <memory>

struct A {
    int value;
};

int main() {
    std::unique_ptr<A> u_ptr1(new A());
    u_ptr1->value;      // dereferencing
    (*u_ptr1).value;   // dereferencing

    auto u_ptr2 = std::make_unique<A>(); // create a new unique pointer

    u_ptr1.reset(new A());           // reset
    auto raw_ptr = u_ptr1.release(); // release
    delete[] raw_ptr;

    std::unique_ptr<A[]> u_ptr3(new A[10]);
    auto& obj = u_ptr3[3];           // access
}
```

## Implements a custom deleter

```
#include <iostream>
#include <memory>

struct A {
    int value;
};

int main() {
    auto DeleteLambda = [](A* x) {
        std::cout << "delete" << std::endl;
        delete x;
    };

    std::unique_ptr<A, decltype(DeleteLambda)>
        x(new A(), DeleteLambda);
} // print "delete"
```

std::shared\_ptr is the pointer type to be used for memory that can be owned by multiple resources at one time

std::shared\_ptr maintains a reference count of pointer objects. Data managed by std::shared\_ptr is only freed when there are no remaining objects pointing to the data

```
#include <iostream>
#include <memory>
struct A {
    int value;
};
int main() {
    std::shared_ptr<A> sh_ptr1(new A());
    std::shared_ptr<A> sh_ptr2(sh_ptr1);
    std::shared_ptr<A> sh_ptr3(new A());
    sh_ptr3 = nullptr; // allowed, the underlying pointer is deallocated
                       // sh_ptr3 : zero references
    sh_ptr2 = sh_ptr1; // allowed // sh_ptr1, sh_ptr2: two references
    sh_ptr2 = std::move(sh_ptr1); // allowed // sh_ptr1: zero references
                                   // sh_ptr2: one references
}
```

## std::shared\_ptr methods

- `get()` returns the underlying pointer
- `operator*` `operator->` dereferences pointer to the managed object
- `use_count()` returns the number of objects referring to the same managed object
- `reset(ptr)` replaces the managed object with `ptr`

Utility method: `std::make_shared()` creates a shared pointer that manages a new object

```
#include <iostream>
#include <memory>
struct A {
    int value;
};

int main() {
    std::shared_ptr<A> sh_ptr1(new A());
    auto sh_ptr2 = std::make_shared<A>(); // std::make_shared
    std::cout << sh_ptr1.use_count(); // print 1

    sh_ptr1 = sh_ptr2; // copy
    // std::shared_ptr<A> sh_ptr2(sh_ptr1); // copy (constructor)
    std::cout << sh_ptr1.use_count(); // print 2
    std::cout << sh_ptr2.use_count(); // print 2

    auto raw_ptr = sh_ptr1.get(); // get
    sh_ptr1.reset(new A()); // reset

    (*sh_ptr1).value = 3; // dereferencing
    sh_ptr1->value = 2; // dereferencing
}
```

A `std::weak_ptr` is simply a `std::shared_ptr` that is allowed to dangle (pointer not deallocated)

```
#include <iostream>
#include <memory>

struct A {
    int value;
};

int main() {
    auto ptr = new A();
    std::weak_ptr<A> w_ptr(ptr);
    std::shared_ptr<A> sh_ptr(new A());

    sh_ptr = nullptr;
    // delete sh_ptr.get(); // double free or corruption

    w_ptr = nullptr;
    delete w_ptr; // ok valid
}
```

It must be converted to `std::shared_ptr` in order to access the referenced object

`std::weak_ptr` methods

- `use_count()` returns the number of objects referring to the same managed object
- `reset(ptr)` replaces the managed object with `ptr`
- `expired()` checks whether the referenced object was already deleted (`true`, `false`)
- `lock()` creates a `std::shared_ptr` that manages the referenced object

```
#include <iostream>
#include <memory>
struct A {
    int value;
};
int main() {
    auto sh_ptr1 = std::make_shared<A>();

    std::cout << sh_ptr1.use_count(); // print 1
    std::weak_ptr<A> w_ptr = sh_ptr1;
    std::cout << w_ptr.use_count(); // print 1

    auto sh_ptr2 = w_ptr.lock();
    std::cout << sh_ptr2.use_count(); // print 2 (sh_ptr1 + sh_ptr2)

    sh_ptr1 = nullptr;
    std::cout << w_ptr.expired(); // print false

    sh_ptr2 = nullptr;
    std::cout << w_ptr.expired(); // print true
}
```

# Concurrency

---

# Overview

C++11 introduces the **Concurrency** library to simplify managing OS threads

```
#include <iostream>
#include <thread>

void f() {
    std::cout << "first thread" << std::endl;
}

int main(){
    std::thread th(f);
    th.join();           // stop the main thread until "th" complete
}
```

How to compile:

```
$g++ -std=c++11 main.cpp -pthread
```

# Example

```
#include <iostream>
#include <thread>
#include <vector>

void f(int id) {
    std::cout << "thread " << id << std::endl;
}

int main() {
    std::vector<std::thread> thread_vect; // thread vector
    for (int i = 0; i < 10; i++)
        thread_vect.push_back( std::thread(&f, i) );

    for (auto& th : thread_vect)
        th.join();

    thread_vect.clear();
    for (int i = 0; i < 10; i++) { // thread + lambda expression
        thread_vect.push_back(
            std::thread( [](){ std::cout << "thread\n"; } ) );
    }
}
```

## Library methods:

- `std::this_thread::get_id()` returns the thread id
- `std::thread::sleep_for( sleep_duration )`  
Blocks the execution of the current thread for at least the specified `sleep_duration`
- `std::thread::hardware_concurrency()` returns the number of concurrent threads supported by the implementation

## Thread object methods:

- `get_id()` returns the thread id
- `join()` waits for a thread to finish its execution
- `detach()` permits the thread to execute independently from the thread handle

```
#include <chrono> // the following program should (not deterministic)
#include <iostream> // produces the output:
#include <thread> // child thread exit
                // main thread exit

int main() {
    using namespace std::chrono_literals;
    std::cout << std::this_thread::get_id();
    std::cout << std::thread::hardware_concurrency(); // e.g. print 6

    auto lambda = []() {
        std::this_thread::sleep_for(1s); // t2
        std::cout << "child thread exit\n";
    };
    std::thread child(lambda);
    child.detach(); // without detach(), child must join() the
                  // main thread (run-time error otherwise)
    std::this_thread::sleep_for(2s); // t1
    std::cout << "main thread exit\n";
}

// if t1 < t2 the should program prints:
// main thread exit
```

# Parameters Passing

Parameters passing *by-value* or *by-pointer* to a thread function works in the same way of a standard function. *Pass-by-reference* requires a special wrapper ( `std::ref` , `std::cref` ) to avoid wrong behaviors

```
#include <iostream>
#include <thread>
void f(int& a, const int& b) {
    a = 7;
    const_cast<int&>(b) = 8;
}
int main() {
    int a = 1, b = 2;
    std::thread th1(f, a, b);           // wrong!!!
    std::cout << a << ", " << b << std::endl; // print 1, 2!!

    std::thread th2(f, std::ref(a), std::cref(b)); // correct
    std::cout << a << ", " << b << std::endl; // print 7, 8!!
    th1.join(); th2.join();
}
```

The following code produces (in general) a value  $< 1000$ :

```
#include <chrono>
#include <iostream>
#include <thread>
#include <vector>
void f(int& value) {
    for (int i = 0; i < 10; i++) {
        value++;
        std::this_thread::sleep_for(std::chrono::milliseconds(10));
    }
}
int main() {
    int value = 0;
    std::vector<std::thread> th_vect;
    for (int i = 0; i < 100; i++)
        th_vect.push_back( std::thread(f, std::ref(value)) );

    for (auto& it : th_vect)
        it.join();
    std::cout << value;
}
```

C++11 provide the `mutex` class as synchronization primitive to protect shared data from being simultaneously accessed by multiple threads

`mutex` methods:

- `lock()` locks the *mutex*, blocks if the *mutex* is not available
- `try_lock()` tries to lock the *mutex*, returns if the *mutex* is not available
- `unlock()` unlocks the *mutex*

More advanced mutex can be found here: [en.cppreference.com/w/cpp/thread](http://en.cppreference.com/w/cpp/thread)

C++ includes three mutex wrappers to provide safe copyable/movable objects:

- `lock_guard` (C++11) implements a strictly scope-based mutex ownership wrapper
- `unique_lock` (C++11) implements movable mutex ownership wrapper
- `shared_lock` (C++14) implements movable shared mutex ownership wrapper

```
#include <chrono>
#include <iostream>
#include <thread>
#include <vector>
void f(int& value, std::mutex& m) {
    for (int i = 0; i < 10; i++) {
        m.lock();
        value++;    // other threads must wait
        m.unlock();
        std::this_thread::sleep_for(std::chrono::milliseconds(10));
    }
}
int main() {
    std::mutex m;
    int value = 0;
    std::vector<std::thread> th_vect;
    for (int i = 0; i < 100; i++)
        th_vect.push_back( std::thread(f, std::ref(value), std::ref(m)) );
    for (auto& it : th_vect)
        it.join();
    std::cout << value;
}
```

# Atomic

`std::atomic` (C++11) template class defines an atomic type that are implemented with lock-free operations (much faster than locks)

```
#include <atomic>
... // include also: chrono, iostream, thread, vector

void f(std::atomic<int>& value) {
    for (int i = 0; i < 10; i++) {
        value++;
        std::this_thread::sleep_for(std::chrono::milliseconds(10));
    }
}

int main() {
    std::atomic<int> value(0);
    std::vector<std::thread> th_vect;
    for (int i = 0; i < 100; i++)
        th_vect.push_back( std::thread(f, std::ref(value)) );
    for (auto& it : th_vect)
        it.join();
    std::cout << value;    // print 1000
}
```

The `future` library provides facilities to obtain values that are returned and to catch exceptions that are thrown by *asynchronous* tasks

Asynchronous call: `std::future async(function, args...)`  
runs a function asynchronously (potentially in a new thread)  
and returns a `std::future` object that will hold the result

`std::future` methods:

- `T get()` returns the result
- `wait()` waits for the result to become available

`async()` can be called with two launch policies for a task executed:

- `std::launch::async` a new thread is launched to execute the task asynchronously
- `std::launch::deferred` the task is executed on the calling thread the first time its result is requested (lazy evaluation)

```
#include <iostream>
#include <vector>
#include <algorithm>
#include <numeric>
#include <future>
template <typename RandomIt>
int parallel_sum(RandomIt beg, RandomIt end) {
    auto len = end - beg;
    if (len < 1000)    // base case
        return std::accumulate(beg, end, 0);

    RandomIt mid = beg + len / 2;
    auto handle = std::async(std::launch::async, // right side
                             parallel_sum<RandomIt>, mid, end);
    int sum = parallel_sum(beg, mid);           // left side
    return sum + handle.get();                 // left + right
}
int main() {
    std::vector<int> v(10000, 1); // init all to 1
    std::cout << "The sum is " << parallel_sum(v.begin(), v.end());
}
```
