Modern C++ Programming

4. Basic Concepts III

Entities and Control Flow

Federico Busato

Table of Contents

Table of Contents

Entities

Entities

A C++ program is set of language-specific *keywords* (`for, if, new, true`, etc.), *identifiers* (symbols for variables, functions, structures, namespaces, etc.), *expressions* defined as sequence of operators, and *literals* (constant value tokens)

C++ Entity

An **entity** is a value, object, reference, function, enumerator, type, class member, template, or namespace

Identifiers and *user-defined operators* are the names used to refer to *entities*

Entities also captures the result(s) of an *expression*

Preprocessor macros are not C++ entities

Declaration and Definition

Declaration/Definition

Declaration/Prototype

A **declaration** (or *prototype*) introduces an *entity* with an *identifier* describing its type and properties

A *declaration* is what the compiler and the linker needs to accept references (usage) to that identifier

Entities can be declared multiple times. All declarations are the same

Definition/Implementation

An entity **definition** is the implementation of a declaration. It defines the properties and the behavior of the entity

For each entity, only a single *definition* is allowed

Declaration/Definition Function Example

```cpp
void f(int a, char* b);  // function declaration

void f(int a, char*) {   // function definition
    ...                  // "b" can be omitted if not used
}

void f(int a, char* b);  // function declaration
                         // multiple declarations is valid

f(3, "abc");             // usage
```

```cpp
void g();  // function declaration

g();       // linking error "g" is not defined
```

Declaration/Definition `struct` Example

A declaration without a concrete implementation is an incomplete type (as `void`)

```
struct A;   // declaration 1
struct A;   // declaration 2 (ok)

struct B {  // declaration and definition
    int b;
//  A   x;  // compile error incomplete type
    A*  y;  // ok, pointer to incomplete type
};

struct A {  // definition
    char c;
}
```

Enumerators

Enumerator - `enum`

Enumerator

An **enumerator** enum is a data type that groups a set of named integral constants

```cpp
enum color_t { BLACK, BLUE, GREEN };

color_t color = BLUE;
cout << (color == BLACK); // print false
```

The problem:

```cpp
enum color_t { BLACK, BLUE, GREEN };
enum fruit_t { APPLE, CHERRY };

color_t color = BLACK;      // int: 0
fruit_t fruit = APPLE;      // int: 0
bool    b     = (color == fruit); // print 'true'!!
// and, most importantly, does the match between a color and
// a fruit make any sense?
```

Strongly Typed Enumerator - `enum class`

enum class (C++11)

enum class (scoped enum) data type is a *type safe* enumerator that is not implicitly
convertible to int

```cpp
enum class Color { BLACK, BLUE, GREEN };
enum class Fruit { APPLE, CHERRY };

Color color = Color::BLUE;
Fruit fruit = Fruit::APPLE;

// bool b = (color == fruit) compile error we are trying to match colors with fruits
//                           BUT, they are different things entirely
// int a1 = Color::GREEN;              compile error
// int a2 = Color::RED + Color::GREEN; compile error
   int a3 = (int) Color::GREEN;        // ok, explicit conversion
```

enum/enum class **Features**

- **enum/enum class** can be compared

```cpp
enum class Color   { RED, GREEN, BLUE };
cout << (Color::RED < Color::GREEN); // print true
```

- **enum/enum class** are automatically enumerated in increasing order

```cpp
enum class Color { RED, GREEN = -1, BLUE, BLACK };
//                  (0)   (-1)     (0)   (1)
Color::RED == Color::BLUE; // true
```

- **enum/enum class** can contain alias

```cpp
enum class Device { PC = 0, COMPUTER = 0, PRINTER };
```

- C++11 **enum/enum class** allows setting the underlying type

```cpp
enum class Color : int8_t { RED, GREEN, BLUE };
```

- C++17 `enum class` supports *direct-list-initialization*

```cpp
enum class Color { RED, GREEN, BLUE };
Color a{2}; // ok, equal to Color:BLUE
```

- C++17 `enum/enum class` support *attributes*

```cpp
enum class Color { RED, GREEN, BLUE [[deprecated]] };
auto x = Color::BLUE; // compiler warning
```

enum class Features - C++20

- C++20 allows introducing the enumerator identifiers into the local scope to decrease the verbosity

```cpp
enum class Color { RED, GREEN, BLUE };

switch (x) {
    using enum Color; // C++20
    case RED:
    case GREEN:
    case BLUE:
}
```

enum/enum class - **Common Errors**

- **enum/enum class** should be always initialized

```cpp
enum class Color { RED, GREEN, BLUE };

Color my_color;  // "my_color" may be outside RED, GREEN, BLUE!!
```

- C++17 Cast from *out-of-range values* respect to the *underlying type* of **enum/enum class** leads to undefined behavior

```cpp
enum Color : uint8_t { RED, GREEN, BLUE };

Color value = 256; // undefined behavior
```

- C++17 `constexpr` expressions don't allow *out-of-range values* for (only) `enum` without explicit *underlying type*

```
enum        Color      { RED };
enum        Fruit : int { APPLE };
enum class Device      { PC };

// constexpr Color  a1 = (Color)  -1; compile error
   const     Color  a2 = (Color)  -1; // ok
   constexpr Fruit  a3 = (Fruit)  -1; // ok
   constexpr Device a4 = (Device) -1; // ok
```

Construction Rules for enum class Values

struct, Bitfield, and union

A struct (*structure*) aggregates different variables into a single unit

```
struct A {
    int   x;
    char  y;
};
```

It is possible to declare one or more variables after the definition of a struct

```
struct A {
    int x;
} a, b;
```

Enumerators can be declared within a struct without a name

```
struct A {
    enum {X, Y}
};
A::X;
```

It is possible to declare a struct in a local scope (with some restrictions), e.g. function scope

```
int f() {
    struct A {
        int x;
    } a;
    return a.x;
}
```

Anonymous and Unnamed `struct`[*]

Unnamed `struct` : a structured without a name, but with an associated type

Anonymous `struct` : a structured without a name and type

The C++ standard allows *unnamed* `struct` but, contrary to C, does <u>not</u> allow *anonymous* `struct` (i.e. without a name)

```cpp
struct {
   int x;
} my_struct;          // unnamed struct, ok

struct S {
   int x;
   struct { int y; }; // anonymous struct, compiler warning with -Wpedantic
};                     // -Wpedantic: diagnose use of non-strict ISO C++ extensions
```

Bitfield

Bitfield

A **bitfield** is a variable of a structure with a predefined bit width. A bitfield can hold bits instead bytes

```
struct S1 {
    int b1 : 10;  // range [0, 1023]
    int b2 : 10;  // range [0, 1023]
    int b3 : 8;   // range [0, 255]
}; // sizeof(S1): 4 bytes

struct S2 {
    int b1 : 10;
    int    : 0;   // reset: force the next field
    int b2 : 10;  //        to start at bit 32
}; // sizeof(S1): 8 bytes
```

Union

A union is a special data type that allows to store different data types in the same memory location

- The union is only as big as necessary to hold its *largest* data member
- The union is a kind of *"overlapping"* storage

```
union A {
    int  x;
    char y;
};
```

```
A a;
a.x = 0xAABBCCDD
```

x	0xDD	0xCC	0xBB	0xAA
y	0xDD			

<u>Note</u>: little endian

```
union A {
    int  x;
    char y;
}; // sizeof(A): 4

A a;
a.x = 1023;   // bits: 00..000001111111111
a.y = 0;      // bits: 00..000001100000000
cout << a.x;  // print 512 + 256 = 768
```

NOTE: Little-Endian encoding maps the bytes of a value in memory in the reverse order. `y` maps to the last byte of `x`

Contrary to `struct`, C++ allows *anonymous* `union` (i.e. without a name)

C++17 introduces `std::variant` to represent a *type-safe union*

Control Flow

if Statement

The `if` statement executes the first branch if the specified condition is evaluated to `true`, the second branch otherwise

- *Short-circuiting*:

```
if (<true expression> r| array[-1] == 0)
... // no error!! even though index is -1
    // left-to-right evaluation
```

- *Ternary operator*:

```
<cond> ? <expression1> : <expression2>
```

$<expression1>$ and $<expression2>$ must return a value of the same or convertible type

```
int value = (a == b) ? a : (b == c ? b : 3); // nested
```

`for` and `while` **Loops**

- `for`
```
for ([init]; [cond]; [increment]) {
    ...
}
```
To use when number of iterations <u>is known</u>

- `while`
```
while (cond) {
    ...
}
```
To use when number of iterations <u>is not known</u>

- `do while`
```
do {
...
} while (cond);
```
To use when number of iterations is not known, but there is <u>at least one iteration</u>

`for` Loop Features and Jump Statements

- C++ allows "in loop" definitions:
```cpp
for (int i = 0, k = 0; i < 10; i++, k += 2)
    ...
```

- Infinite loop:
```cpp
for (;;)   // also while(true);
    ...
```

- Jump statements (break, continue, return):
```cpp
for (int i = 0; i < 10; i++) {
    if (<condition>)
        break;     // exit from the loop
    if (<condition>)
        continue;  // continue with a new iteration and exec. i++
    return;        // exit from the function
}
```

C++11 introduces the **range-based `for` loop** to simplify the verbosity of traditional `for` loop constructs. They are equivalent to the `for` loop operating over a range of values, but **safer**

The range-based `for` loop avoids the user to specify start, end, and increment of the loop

```cpp
for (int v : { 3, 2, 1 }) // INITIALIZER LIST
    cout << v << " ";      // print: 3 2 1

int values[] = { 3, 2, 1 };
for (int v : values)      // ARRAY OF VALUES
    cout << v << " ";      // print: 3 2 1

for (auto c : "abcd")     // RAW STRING
    cout << c << " ";      // print: a b c d
```

Range-based for loop can be applied in three cases:

- Fixed-size array `int array[3]` , `"abcd"`

- Branch Initializer List `{1, 2, 3}`

- Any object with `begin()` and `end()` methods

```cpp
std::vector vec{1, 2, 3, 4};

for (auto x : vec) {
   cout << x << ", ";
// print:  "1, 2, 3, 4"
```

```cpp
int matrix[2][4];
for (auto& row : matrix) {
    for (auto element : row)
        cout << "@";
    cout << "\n";
}
// print:  @@@@
//         @@@@
```

C++17 extends the concept of **range-based loop** for *structure binding*

```cpp
struct A {
    int x;
    int y;
};

A array[] = { {1,2}, {5,6}, {7,1} };
for (auto [x1, y1] : array)
    cout << x1 << "," << y1 << "  ";  // print: 1,2  5,6  7,1
```

The switch statement evaluates an expression (int , char , enum class , enum)
and executes the statement associated with the matching case value

```cpp
char x = ...
switch (x) {
    case 'a': y = 1; break;
    default:  return -1;
}
return y;
```

Switch scope:

```cpp
int x = 1;
switch (1) {
    case 0: int x;       // nearest scope
    case 1: cout << x;   // undefined!!
    case 2: { int y; }   // ok
// case 3: cout << y;    // compile error
}
```

26/34

Fall-through:

```
MyEnum x
int y = 0;
switch (x) {
    case MyEnum::A:      // fall-through
    case MyEnum::B:      // fall-through
    case MyEnum::C: return 0;
    default: return -1;
}
```

C++17 `[[fallthrough]]` attribute

```
char x = ...
switch (x) {
    case 'a': x++;
               [[fallthrough]]; // C++17: avoid warning
    case 'b': return 0;
    default:  return -1;
}
```

Control Flow with Initializing Statement

Control flow with **initializing statement** aims at simplifying complex actions before the condition evaluation and restrict the scope of a variable which is visible only in the control flow body

C++17 introduces `if` statement with initializer

```cpp
if (int ret = x + y; ret < 10)
    cout << ret;
```

C++17 introduces `switch` statement with initializer

```cpp
switch (auto i = f(); x) {
    case 1: return i + x;
```

C++20 introduces `range-for loop` statement with initializer

```cpp
for (int i = 0; auto x : {'A', 'B', 'C'})
    cout << i++ << ":" << x << " ";  // print: 1:A  2:B  3:C
```

When goto could be useful:

```cpp
bool flag = true;
for (int i = 0; i < N && flag; i++) {
    for (int j = 0; j < M && flag; j++) {
        if (<condition>)
            flag = false;
    }
}
```
become:

```cpp
for (int i = 0; i < N; i++) {
    for (int j = 0; j < M; j++) {
        if (<condition>)
            goto LABEL;
    }
}
LABEL: ;
```

Best solution:

```cpp
bool my_function(int M, int M) {
    for (int i = 0; i < N; i++) {
        for (int j = 0; j < M; j++) {
            if (<condition>)
                return false;
        }
    }
    return true;
}
```
Junior: what's wrong with goto command?

goto command:

Most compilers issue a warning when a variable is unused. C++17 introduces `[[maybe_unused]]` attribute to prevent this warning in a portable way

```cpp
int f(int value) {
    [[maybe_unused]] int x = value;
#if defined(ENABLE_SQUARE_PATH)
    return x * x;
#else
//  static_cast<void>(x); // before C++17
    return 0;
#endif
}
```

```cpp
template<typename T>
int f([[maybe_unused]] T value) {
    if constexpr (sizeof(value) >= 4)
        return 1;
    else
        return 2;
}

template<typename T>
int g([[maybe_unused]] T value) {
    using R = decltype(value);
    return R{};
}

// MSVC issues a warning if [[maybe_unused]] is not applied
```
