

# Modern C++ Programming

## 8. C++ OBJECT ORIENTED PROGRAMMING II

---

*Federico Busato*

University of Verona, Dept. of Computer Science  
2020, v3.0

## 1 Polymorphism

- virtual Methods
- Virtual Table
- override Keyword
- final Keyword
- Common Errors
- Pure Virtual Method
- Abstract Class and Interface

# Table of Context

## 2 Operator Overloading

- Overview
- Binary Operator
- stream operator<<
- function call operator()
- Conversion operator type()
- Assignment operator type=

## 3 C++ Special Objects

- Aggregate
- Trivial Class
- Standard-Layout Class
- Plain Old Data (POD)
- Hierarchy

# Polymorphism

---

# Polymorphism

## Polymorphism

In object-oriented programming, **polymorphism** (meaning “having multiple forms”) is the capability of an object of *mutating* its behavior in accordance with the specific usage *context*

- At run-time, objects of a *derived class* may be treated as objects of a *base class*
- **Base** classes may define and implement polymorphic ( *virtual* ) methods, and **derived** classes can override them, which means they provide their own implementations which are invoked at run-time depending on the context

**Overloading** is a form of static polymorphism (compile-time polymorphism)

In C++ the term *polymorphic* is strongly associated with dynamic polymorphism (overriding)

## Polymorphism (the problem)

```
struct A {  
    void f() { std::cout << "A"; }  
};  
  
struct B : A { // B extends A (B does something more than A)  
    void f() { std::cout << "B"; }  
};  
  
void g(A& a) { a.f(); } // accepts A and B  
  
void h(B& b) { b.f(); } // accepts only B  
  
int main() {  
    A a; B b;  
    g(a); // print "A"  
    g(b); // print "A" not "B"!!!  
    // h(a); // compile error!!  
    h(b); // print "B"  
}
```

# Function Binding

Connecting the function call to the function body is called *Binding*

- In **Early Binding** or *Static Binding* or *Compile-time Binding*, the compiler identifies the type of object at compile-time
- In **Late Binding** or *Dynamic Binding* or *Run-time binding*, the compiler identifies the type of object at run-time and *then* matches the function call with the correct function definition

In C++ **late binding** can be achieved by declaring a **virtual** function

- *Early binding*: the program can jump directly to the function address
- *Late binding*: the program has to read the address held in the pointer and then jump to that address (less efficient since it involves an extra level of indirection)

## Polymorphism (virtual method)

```
struct A {  
    virtual void f() { std::cout << "A"; }  
}; // now "f()" is virtual, evaluated at run-time  
  
struct B : A { // B extends A (B does something more than A)  
    void f() { std::cout << "B"; }  
}; // now "B::f()" override "A::f()", evaluated at run-time  
  
void g(A& a) { a.f(); } // accepts A and B  
  
void h(B& b) { b.f(); } // accepts only B  
  
int main() {  
    A a; B b;  
    g(a);      // print "A"  
    g(b);      // NOW, print "B"!!!  
    h(b);      // print "B"  
}
```

# When virtual works

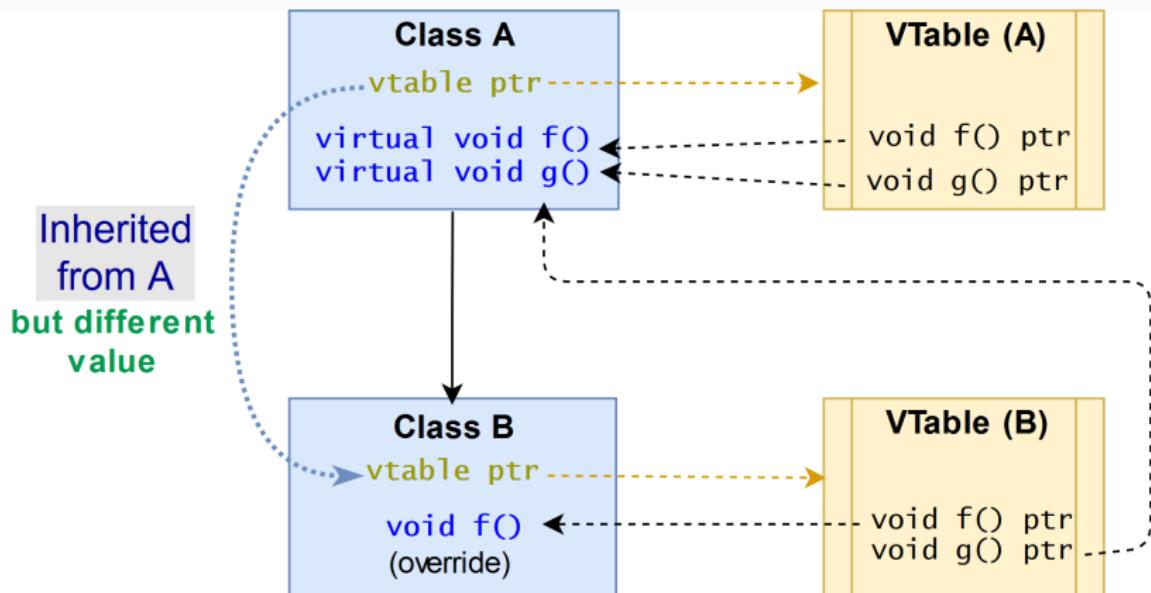

```
struct A {  
    virtual void f() { std::cout << "A"; }  
    virtual void g() {} // see next slide  
};  
struct B : A {  
    void f() { std::cout << "B"; }  
};  
void g(A a) { a.f(); }  
void h(A& a) { a.f(); }  
void p(A* a) { a->f(); }  
  
int main() {  
    A a; B b;  
    a.f();          // print "A"  
    b.f();          // print "B"  
    A* ax1 = &b;   // memory address conversion  
    ax1->f();      // print "B"  
    g(b);          // print "A" (cast to A)  
    h(b);          // print "B"  
    p(&b);         // print "B"  
}
```

## vtable

The **virtual table** (vtable) is a lookup table of functions used to resolve function calls and support *dynamic dispatch* (late binding)

A *virtual table* contains one entry for each `virtual` function that can be called by objects of the class. Each entry in this table is simply a function pointer that points to the *most-derived* function accessible by that class

The compiler adds a *hidden* pointer to the base class which points to the virtual table for that class (`sizeof` considers the vtable pointer)

## Virtual Method Notes

`virtual` classes allocate one extra pointer (hidden)

```
class A {  
    double x;  
    virtual void f1();  
    virtual void f2();  
}  
  
class B : A {  
    virtual void f1();  
}  
  
sizeof(A) = sizeof(double) + 1 * sizeof(pointer) // 16  
sizeof(B) = sizeof(A) // 16
```

The `virtual` keyword is not necessary in derived classes, but it improves *readability* and clearly advertises the fact to the user that the function is virtual

# override Keyword

## override Keyword

The `override` keyword (C++11) ensures that the function is virtual and is overriding a virtual function from a base class

It forces the compiler to check the base class to see if there is a virtual function with this exact signature

- `override` implies `virtual` (`virtual` should be omitted)

```
struct A {  
    virtual void f(int a);           // a "float" value is casted to "int"  
};                                // see*  
  
struct B : A {  
    void f(int a) override;          // ok  
    void f(float a);                // (still) very dangerous!! see*  
//    void f(float a) override;      // compile error!! not safe  
//    void f(int a) const override; // compile error!! not safe  
};  
// *f(3.3f) has different behavior between A and B
```

# final Keyword

## final Keyword

The `final` keyword (C++11) prevent inheriting from classes or prevent overriding methods in derived classes

```
struct A {  
    virtual void f(int a) final; // "final" method  
};  
  
struct B : A {  
// void f(int a); // compile error!! f(int) is "final"  
    void f(float a); // dangerous!! (still possible)  
}; // "override" prevents these errors  
  
struct C final { // cannot be extended  
};  
// struct D : C { // compile error!! C is "final"  
// };
```

# Virtual Methods (Common Error 1)

All classes with at least one `virtual` method should declare  
a `virtual destructor`

```
struct A {
    ~A() { std::cout << "A"; }      // <-- here the problem (not virtual)
    virtual void f(int a) {}
};

struct B : A {
    int* array;
    B() { array = new int[1000000]; }
    ~B() {
        delete[] array;
        std::cout << "B";
    }
};
void g(A* a) {
    delete a;      // call ~A()
}
int main() {
    B* b = new B;
    g(b);         // without virtual, ~B() is not called
}                      // g() prints only "A" -> huge memory leak!!
```

# Virtual Methods (Common Error 2)

## Do not call virtual methods in constructor and destructor

- *Constructor:* The derived class is not ready until constructor is completed
- *Destructor:* The derived class could be already destroyed

```
struct A {  
    A() { f(); } // what instance is called? "B" is not ready  
              // it calls A::f(), even though A::f() is virtual  
    virtual void f() { std::cout << "A"; }  
};  
  
struct B : A {  
    B() : A() {} // call A()      (A() call may be also implicit)  
  
    void f() { std::cout << "B"; }  
};  
  
int main() {  
    B b;      // call B()  
}          // print "A", not "B"!!
```

# Virtual Methods (Common Error 3)

## Do not use default parameters in virtual methods

Default parameters are not inherited

```
struct A {  
    virtual void f(int i = 5) { std::cout << "A::" << i << "\n"; }  
    virtual void g(int i = 5) { std::cout << "A::" << i << "\n"; }  
};  
  
struct B : A {  
    void f(int i = 3) { std::cout << "B::" << i << "\n"; }  
    void g(int i)      { std::cout << "B::" << i << "\n"; }  
};  
  
int main() {  
    A* a = new A();  
    a->f();           // ok, print "A::5"  
    B* b = new B();  
    b->f();           // ok, print "B::3"  
    A* bb = new B();  
    bb->f();          // !!! print "B::5" // the virtual table of A  
                      // contains f(int i = 5) and  
    bb->g();          // !!! print "B::5" // g(int i = 5) but it points  
                      // to B implementations  
}
```

## Pure Virtual Method

A **pure virtual method** is a function that must be implemented in derived classes (concrete implementation)

Pure virtual functions can have or not have a body

```
struct A {  
    virtual void f(int x) = 0; // pure virtual without body  
    virtual void g(int x) = 0; // pure virtual with body  
};  
  
void A::g(int x) {} // pure virtual implementation (body) for g()  
  
struct B : A {  
    void f(int x) {} // must be implemented  
    void g(int x) {} // must be implemented  
};
```

If a virtual method is not implemented in derived class, it is implicitly declared pure virtual

```
struct A {  
    virtual void f(int x) = 0;  
};  
  
struct B : A {  
//    virtual void f(int x) = 0; // implicitly declared  
};  
  
struct C : B {  
    void f(int x) override {} // implemented  
};  
  
int main() {  
    C c;  
    c.f(3); // ok  
}
```

# Abstract Class and Interface

- A class is **abstract** if it has at least one *pure virtual* function
- A class is **interface** if it has only *pure virtual* functions and optionally (*suggested*) a virtual destructor. Interfaces do not have implementation or data

```
struct A {           // INTERFACE
    virtual ~A();   // to implement
    virtual void f(int x) = 0;
};

struct B {           // ABSTRACT CLASS
    B() {}         // abstract classes may have a constructor
    virtual void g(int x) = 0; // at least one pure virtual
protected:
    int x;          // additional data
};
```

# Virtual Methods (Virtual Constructor)

Virtual Constructor is not supported in C++, but can be emulated by using other `virtual` methods

```
struct A {
    virtual ~A() {} // A virtual destructor
    virtual A clone() const = 0; // Uses the copy constructor
    virtual A create() const = 0; // Uses the default constructor
};

struct B : A {
    B clone() const { // Covariant Return Types
        return B(*this); // (different from A::clone())
    }

    B create() const { // Covariant Return Types
        return B(); // (different from A::create())
    }
};

void f(A& a) {
    B b = a.clone(); // ok
}
```

# Operator Overloading

---

# Operator Overloading

## Operator Overloading

**Operator overloading** is a special case of polymorphism in which some *operators* are treated as polymorphic functions and have different behaviors depending on the type of its arguments

```
struct Point {  
    int x, y;  
    Point(int x1, int y1) : x(x1), y(y1) {}  
  
    Point operator+(const Point& p) const {  
        return Point(x + p.x, y + p.y);  
    }  
};  
  
int main() {  
    Point a(1, 2);  
    Point b(5, 3);  
    Point c = a + b; // "c" is (6, 5)  
}
```

# Operator Overloading

Syntax: `operator@`

Categories not in bold are rarely used in practice

---

**Arithmetic:**

+ - \* \ % ++ --

**Comparison:**

== != < <= > >=

Bitwise:

| & ^ ~ << >>

Logical:

! && ||

**Compound assignment:**

+= <<= \*= , etc.

**Subscript:**

[]

Address-of, Reference,

& -> ->\* \*

Dereferencing:

Memory:

new new[] delete delete[]

Comma:

,

---

Operators which cannot be overloaded: ? . .\* :: sizeof typeid 21/40

# Notes

- **Increment, Decrement:** *Prefix* and *Postfix* notation

```
struct A {  
    A& operator++() { // prefix: ++obj  
        ...  
        return *this;  
    }  
    A operator++(A& a); // postfix: obj++  
}; // NOTE: return the old copy of "this"
```

- **Array subscript** operator accepts anything (not only integer)

```
struct A {  
    int& operator[](char c); // read/write  
    const int& operator[](char c) const; // read, "const A a;"  
};  
// A a; a['v'] = 3;
```

- Operators preserve precedence and **short-circuit** properties (e.g. ^)
- **operator<** is used in comparison procedures ( `std::sort` )

# Binary Operator

Binary Operators should be implemented as friend methods

```
class A {};
class C {};

struct B : public A {
    bool operator==(const A& x) { return true; }
};

class D : public C {
    friend bool operator==(const C& x, const C& y);
};

bool operator==(const C& x, const C& y); { return true; }

int main() {
    A a; B b; C c; D d;
    b == a; // ok
// a == b; // compile error!! // friend is useful to access
// private fields
    c == d; // ok
    d == c; // ok
}
```

## Special Operators (iostream operator<<)

The **stream operations** can be overloaded to perform input and output for user-defined types

```
#include <iostream>
struct Point {
    int x, y;

    // may be also directly defined inside Point
    friend std::ostream& operator<<(std::ostream& stream,
                                         const Point& point);
};

std::ostream& operator<<(std::ostream& stream,
                           const Point& point) {
    stream << "(" << point.x << "," << point.y << ")";
    return stream;
}

int main() {
    Point point { 1, 2 };
    std::cout << point; // print "(1, 2)"
}
```

## Special Operators (function call operator())

The **function call operator** is generally overloaded to create objects which behave like functions, or for classes that have a primary operation

Many algorithms (included std library) accept objects of such types to customize behavior

```
#include <iostream>
#include <numeric> // for std::accumulate
struct Multiply {
    int operator()(int a, int b) const {
        return a * b;
    }
};

int main() {
    int array[] = { 2, 3, 4 };
    int mul = std::accumulate(array, array + 3, 1, Multiply());
    std::cout << mul; // 24
}
```

## Special Operators (Conversion operator type())

**Conversion operators** enable objects of a class to be either implicitly (coercion) or explicitly (casting) converted to another type

```
class MyBool {
    int a;
public:
    MyBool(int a1) : a(a1) {}

    operator bool()(const MyBool& b) const {
        return b.a == 0;      // implicit return type
    }
};

int main() {
    MyBool my_bool { 3 };
    bool b = my_bool;    // b = false, call operator bool()
}
```

## Special Operators (Conversion operator type() + explicit)

**Conversion operators** can be marked explicit to prevent implicit conversions:

```
struct A {  
    operator bool() { return true; }  
};  
  
struct B {  
    explicit operator bool() { return true; }  
};  
  
int main() {  
    A a;  
    B b;  
    bool c = a;  
    // bool c = b; // compile error!! explicit  
    bool c = static_cast<bool>(b);  
}
```

The **assignment operator** (`operator=`) is used to copy values from one object to another *already existing* object

```
#include <algorithm> //std::fill, std::copy
struct A {
    char* array;
    int size;

    A(int size1, char value) : size(size1) {
        array = new char[size];
        std::fill(array, array + size, value);
    }
    ~A() { delete[] array; }

    A& operator=(const A& x) { .... } // see next slide
};

int main() {
    A obj(5, 'o'); // ["ooooo"]
    A a(3, 'b'); // ["bbb"]
    obj = a; // obj = ["bbb"]
}
```

- First option:

```
A& operator=(const A& x) {  
    if (this == &x)          // Check for self assignment  
        return *this;  
    delete[] array;         // delete everything from this  
    array = new int[x.size];  
    std::copy(x.array, x.array + size, array); // copy  
    return *this;  
}
```

- Second option (less intuitive):

```
A& operator=(A x) { // pass by value: need a copy constructor  
    swap(this, x);   // now we need a swap function for A  
    return *this;    // see next slide  
}                  // x is destroyed at the end
```

- Swap method:

```
friend void swap(A& x, A& y) {  
    using std::swap;  
    swap(x.size, y.size);  
    swap(x.array, y.Array);  
}
```

- **why using std::swap?** if swap(x, y) finds a better match, it will use that instead of std::swap
- **why friend?** it allows the function to be used from outside the structure/class scope

# C++ Special Objects

---

## Aggregate

An **aggregate** is a type which supports *aggregate initialization* (form of list-initialization) through curly braces syntax {}

An aggregate is an *array* or a *class* with

- No user-provided constructors (all)
- No private/protected non-static data members
- No base classes
- No virtual functions (standard functions allowed)
- \* No *brace-or-equal-initializers* for non-static data members  
(until C++14)

No restrictions:

- Non-static data member (can be also not aggregate)
- Static data members

```
struct NotAggregate1 {  
    NotAggregate1();           // No constructors  
    virtual void f();         // No virtual functions  
};  
  
class NotAggregate2 : NotAggregate1 { // No base class  
    int x;                   // x is private  
};  
  
struct Aggregate1 {  
    int x;  
    int y[3];  
    int z { 3 };           // only C++14  
};  
  
struct Aggregate2 {  
    Aggregate1() = default; // ok, defaulted constructor  
    NotAggregate2 x;        // ok, public member  
    Aggregate2& operator=(const& Aggregate2 obj); // ok  
private:                      // copy-assignment  
    void f() {} // ok, private function (no data member)  
};
```

```
struct Aggregate1 {  
    int x;  
    struct Aggregate2 {  
        int a;  
        int b[3];  
    } y;  
};  
  
int main() {  
    int array1[3] = { 1, 2, 3 };  
    int array2[3] = { 1, 2, 3 };  
    Aggregate1 agg1 = { 1, { 2, { 3, 4, 5 } } };  
    Aggregate1 agg2 = { 1, { 2, { 3, 4, 5 } } };  
    Aggregate1 agg3 = { 1, 2, 3, 4, 5 };  
}
```

## Trivial Class

A **Trivial Class** is a class *trivial copyable* (supports `memcpy`)

### Trivial copyable:

- No user-provided copy/move/default constructors and *destructor*
- No user-provided copy/move assignment operators
- No virtual functions (standard functions allowed) or virtual base classes
- No *brace-or-equal-initializers* for non-static data members
- All non-static members are trivial (recursively for members)

### No restrictions:

- Other user-declared constructors different from default
- Static data members
- Protected/Private members

```
struct NonTrivial1 {
    int y { 3 };           // brace-or-equal-initializers

    NonTrivial1();         // user-provided constructor
    virtual void f();     // virtual function
};

struct Trivial1 {
    Trivial1() = default;   // defaulted constructor
    int x;
    void f();
private:
    int z; // ok, private
};

struct Trivial2 : Trivial1 { // base class is trivial
    int Trivial1[3];       // array of trivials is trivial
};
```

## Standard-Layout

A **standard-layout class** is a class with the same memory layout of the equivalent C struct or union (useful for communicating with other languages)

### Standard-layout class

- No virtual functions or virtual base classes
- Recursively on non-static members, base and derived classes
- Only one control access (public/protected/private) for non-static data members
- No base classes of the same type as the first non-static data member
  - (a) No non-static data members in the *most derived* class and at *most one base* class with non-static data members
  - (b) No base classes with non-static data members

```
struct StandardLayout1 {  
    StandardLayout1(); // user-provided constructor  
    int x;  
    void f();          // non-virtual function  
};  
  
class StandardLayout2 : StandardLayout1 {  
    int x, y;          // both are private  
    StandardLayout1 y; // can have members of base type  
                      // if they are not the first  
};  
  
struct StandardLayout3 { } // empty  
  
struct StandardLayout4 : StandardLayout2, StandardLayout3 {  
    // can use multiple inheritance as long only  
    // one class in the hierarchy has non-static data members  
};
```

## Plain Old Data (POD)

C++11, C++14 Standard-Layout (s) + Trivial copyable (t)

- (t) No user-provided copy/move/default constructors and destructor
- (t) No user-provided copy/move assignment operators
- (t) No virtual functions or virtual base classes
- (t) No *brace-or-equal-initializers* for non-static data member
- (s) Recursively on non-static members, base and derived classes
- (s) Only one control access (public/protected/private) for non-static data members
- (s) No base classes of the same type as the first non-static data member
- (s)a No non-static data members in the *most derived* class and at *most one base* class with non-static data members
- (s)b No base classes with non-static data members

# C++ std Utilities

C++11 provides three utilities to check if a type is POD, Trivial Copyable, Standard-Layout

- `std::is_pod` checks for POD
- `std::is_trivially_copyable` checks for trivial copyable
- `std::is_standard_layout` checks for standard-layout

```
#include <type_traits>
struct A {
    int x;
private:
    int y;
};
int main() {
    std::cout << std::is_trivially_copyable<A>::value; // true
    std::cout << std::is_standard_layout<A>::value; // false
    std::cout << std::is_pod<A>::value; // false
}
```

# Special Objects Hierarchy
